alleleCount      *~~function to do ... ~~*

---

### Description

~~ A concise (1-5 lines) description of what the function does. ~~

### Usage

```
alleleCount(object, ...)
```

### Arguments

```
object      ~~Describe object here~~
...         ~~Describe ... here~~
```

**Details**

~~ If necessary, more details than the description above ~~

**Value**

~Describe the value returned If it is a LIST, use

comp1            Description of 'comp1'

comp2            Description of 'comp2'

...

**Note**

~~further notes~~

**Author(s)**

~~who you are~~

alleleSummary      *Summary of allele information*

---

**Description**

Summary of allele information.

**Usage**

```
alleleSummary(object,
               by = NULL,
               confidence = 0.95,
               alpha = 1 - confidence,
               show = TRUE,
               verbose = FALSE,
               includeOverall = FALSE,
               omitRepeats = TRUE,
               ...)
```

**Arguments**

object	geneSet object
by	optional column name, by which the summary is desired. Default is NULL.
confidence	confidence intervals of Genotype frequencies within each marker (default is 95%)
alpha	Type -1 error rate = (1- confidence)
show	No longer used
verbose	Logical value (TRUE/FALSE), showing whether every 50th marker should be printed, default = FALSE
includeOverall	logical value (TRUE/FALSE) indicating whether overall summary is also needed, default = FALSE
omitRepeats	logical value (TRUE/FALSE) indicating whether Gene name and marker name should be printed repeatedly for each Genotype, default = TRUE
...	Optional arguments

**Author(s)**

Nitin Jain (nitin.jain@pfizer.com)

**Examples**

```
library(GeneticsBase)
data(CAMP)

temp <- alleleSummary(CAMP)

print(temp) # display
txt(temp, filename="alleleSummary.txt") # txt file
html(temp, filename="alleleSummary.html") # html file
latex(temp, filename="alleleSummary.tex") # latex file
```

ALZH

*Sample from National Institute of Mental Health (NIMH) Genetics Initiative Alzheimer's Disease*

---

**Description**

Sample from National Institute of Mental Health (NIMH) Genetics Initiative Alzheimer's Disease

**Usage**

```
data(ALZH)
```

**Format**

Object of class 'geneSet'

**Details**

"This data set is a subsample from the National Institute of Mental Health (NIMH) Genetics Initiative Alzheimer's Disease (AD) Sample. The ascertainment and assessment of AD families collected have been discussed in Blacker et al. (1997). None of the families in this data set have parental genotype information; practically all of them have both affected and unaffected offspring. In total there are 901 individuals contained in 301 nuclear families.

"Acknowledgements: We thank Genetics and Aging Research Unit, Rudolph E. Tanzi, PhD, Director, for providing the data.

"Genotypes

"The pedigree file, Alzh.ped, contains genotype information for two candidate genes, apoe and a2m. The apoe gene is multi-allelic, while the a2m gene is bi-allelic. The dataset also contains the affection status (2=affected, 1=unaffected, 0=missing).

"Phenotypes

"We only will be using the Alzheimer dataset to examine affection status, which is contained in the pedigree file, thus a phenotype file for these data is not necessary."

(quoted from Lange and Kraft 2005)

---

Armitage

*Cochran-Armitage test for linear trends in proportions and frequencies*

---

**Description**

Cochran-Armitage test for linear trends in proportions and frequencies.

**Usage**

```
Armitage(geneSetObj, method="A")
Armitage.default(pedObj, method="A")
ArmitageTest(x, mem)
```

**Arguments**

geneSetObj	a geneSet object
pedObj	a pedigree object
method	genotype coding method. The default is additive coding (A). The other two available coding methods are recessive coding (R) and dominant coding (D), respectively.
x	a vector of biallelic markers coded by additive, recessive, or dominant model. Denote B as common allele and A as minor allele. <b>additive model:</b> $x=0 - BB; x=1 - AB; x=2 - AA$ <b>recessive model:</b> $x=0 - BB; x=0 - AB; x=2 - AA$ <b>dominant model:</b> $x=0 - BB; x=1 - AB; x=1 - AA$
mem	disease membership. 1 – case; 0 – control

**Value**

The functions `Armitage` and `Armitage.default` return a matrix with `nMarkers` rows and 2 columns, where `nMarkers` is the number of markers. The two columns are test statistic (`stat`) and p-value (`pvalue`), respectively.

The function `ArmitageTest` returns a list of two elements:

<code>stat</code>	test statistic
<code>pvalue</code>	p-value of the test

**Note**

This implementation is based on the documentation at webpage: <http://linkage.rockefeller.edu/pawe3d/help/Linear-trend-test-ncp.html>.

---

as.geneSet	<i>Convert an existing object to a geneSet</i>
------------	--

---

**Description**

Convert an existing object to a geneSet. Methods currently exist only for matrix and data.frame objects.

**Usage**

```
## S3 method for class 'matrix':
as.geneSet(x, ... )
## S3 method for class 'data.frame':
as.geneSet(x,
  gene.columns,
  format=c("single", "adjacent"),
  ploidy=2,
  alleles=NULL,
  sep="/",
  remove.spaces=TRUE,
  reorder=c("freq", "yes", "no", "default", "ascii"),
  allow.partial.missing=FALSE,
  markerNames,
  phase=list(F),
  ...)
```

**Arguments**

x	The matrix or data.frame object to be converted
gene.columns	Names or indexes of columns containing genotypes
format	One of "single", indicating that each specified column contains a complete genotype (e.g. "A/C"), or "adjacent" indicating that sets of ploidy adjacent columns each contain as single allele (e.g. "A", "C")
ploidy	Number of allele copies per genotype. Defaults to 2
alleles	Not currently supported. In the future, this variable will allow specification of the allele strings for each genotype.
sep	A character value or a numeric index vector indicating how alleles are separated within genotypes, defaults to "/". If a character, it indicates that alleles within a genotype are separated by this character (e.g. for "A/C", sep="/"). If a numeric vector (of length ploidy-1), the value(s) indicate which positions separate allele names (e.g. for "AA", sep=1).

<code>remove.spaces</code>	Should whitespace be removed before processing.
<code>reorder</code>	One of "freq", "yes", "no", "default", or "ascii", indicating whether and how alleles should be reordered within genotypes. If <code>reorder="no"</code> , the observed order is preserved (important when phase is known). If <code>reorder="freq"</code> , sort alleles within each individual by observed frequency. If <code>reorder="yes"</code> , sort alleles in the order provided by the <code>alleles</code> argument. If <code>reorder="ascii"</code> , reorder alleles in ASCII order (alphabetical, with all upper case before lower case). The default value is "freq".
<code>allow.partial.missing</code>	Logical value indicating whether a genotype is permitted to be partially missing. When <code>allow.partial.missing=FALSE</code> , if any individual allele is missing within a genotype, the entire genotype will be converted to a missing value. When <code>allow.partial.missing=TRUE</code> , the missingness of individual alleles will be preserved.
<code>markerNames</code>	Character vector of names to use for the genotype columns. This must have the same length as the number of genotype columns.
<code>phase</code>	List indicating whether phase is known for each genotype column. If the list has a single logical entry, this will apply to all genotype columns.
<code>...</code>	Optional arguments.

**Value**

An S4 object of class `geneSet`

```

---

binsearch

*Binary Search*

---

### Description

Search within a specified range to locate an integer parameter which results in the the specified monotonic function obtaining a given value.

### Usage

```
binsearch(fun, range, ..., target = 0, lower = ceiling(min(range)),
          upper = floor(max(range)), maxiter = 100, showiter = FALSE)
```

### Arguments

<code>fun</code>	Monotonic function over which the search will be performed.
<code>range</code>	2-element vector giving the range for the search.
<code>...</code>	Additional parameters to the function <code>fun</code> .
<code>target</code>	Target value for <code>fun</code> . Defaults to 0.
<code>lower</code>	Lower limit of search range. Defaults to <code>min(range)</code> .
<code>upper</code>	Upper limit of search range. Defaults to <code>max(range)</code> .
<code>maxiter</code>	Maximum number of search iterations. Defaults to 100.
<code>showiter</code>	Boolean flag indicating whether the algorithm state should be printed at each iteration. Defaults to FALSE.

### Details

This function implements an extension to the standard binary search algorithm for searching a sorted list. The algorithm has been extended to cope with cases where an exact match is not possible, to detect whether that the function may be monotonic increasing or decreasing and act appropriately, and to detect when the target value is outside the specified range.

The algorithm initializes two variable `lo` and `high` to the extremes values of `range`. It then generates a new value `center` halfway between `lo` and `hi`. If the value of `fun` at `center` exceeds `target`, it becomes the new value for `lo`, otherwise it becomes the new value for `hi`. This process is iterated until `lo` and `hi` are adjacent. If the function at one or the other equals the `target`, this value is returned, otherwise `lo`, `hi`, and the function value at both are returned.

Note that when the specified `target` value falls between integers, the *two* closest values are returned. If the specified `target` falls outside of the specified `range`, the closest endpoint of the range will be returned, and an warning message will be generated. If the maximum number if iterations was reached, the endpoints of the current subset of the range under consideration will be returned.

**Value**

A list containing:

call	How the function was called.
numiter	The number of iterations performed
flag	One of the strings, "Found", "Between Elements", "Maximum number of iterations reached", "Reached lower boundary", or "Reached upper boundary."
where	One or two values indicating where the search terminated.
value	Value of the function <code>fun</code> at the values of <code>where</code> .

**Note**

This function often returns two values for `where` and `value`. Be sure to check the `flag` parameter to see what these values mean.

**Examples**

```
### Toy examples

# search for x=10
binsearch( function(x) x-10, range=c(0,20) )

# search for x=10.1
binsearch( function(x) x-10.1, range=c(0,20) )

### Classical toy example

# binary search for the index of 'M' among the sorted letters
fun <- function(X) ifelse(LETTERS[X] > 'M', 1,
                          ifelse(LETTERS[X] < 'M', -1, 0 ) )

binsearch( fun, range=1:26 )
# returns $where=13
LETTERS[13]

### Substantive example, from genetics

# Determine the necessary sample size to detect all alleles with
# frequency 0.07 or greater with probability 0.95.
power.fun <- function(N) 1 - gregorius(N=N, freq=0.07)$missprob

binsearch( power.fun, range=c(0,100), target=0.95 )

# equivalent to
gregorius( freq=0.07, missprob=0.05)
```

CAMP

*Genotype data from the Childhood Asthma Management Program (CAMP)*

---

**Description**

"This dataset comprises a collection of parent/child trios in the Childhood Asthma Management Program (CAMP) Ancillary Genetics Study. The CAMP study is a clinical trial of asthmatic children (mild to moderate asthma) who were randomized to three different asthma treatments (CAMP, 1999). The data set includes 699 complete parent/child trios. Some participants are siblings, and there are 2011 persons from 640 nuclear families in total. Both quantitative and qualitative traits are available."

Genotypes:

"The pedigree file, Camp.ped, contains genotype information for eight candidate genes (m709, m654, m47, p46, p79, p252, p491, p523). The last seven markers (all but m709) lie in a haplotype block. All the markers are bi-allelic."

Phenotypes:

"The phenotype file, campz.phe, contains 12 quantitative traits (zposfevp, zposfvc, zlogpc20, zamfmea, zpmpfmea, zbdabs, zfevbd, zbdpred, zsxcm, ztoteos, zlogige, zncorpos). All of the phenotypes have been mean centered and standardized. The fev (forced expiratory volume) and fvc (forced vital capacity) variables refer to the amount of air that can be expelled from the lungs. The pc20 variable refers to the amount of irritant required to cause a 20% drop in fev. The toteos variable refers to total eosinophil (a white blood cell) count, and Ige is a measurement of allergen reactivity."

(quoted from Lange and Kraft 2005)

**Usage**

```
data(CAMP)
```

**Format**

Object to class 'geneSet'. Covariate information described above.

ci.balance	<i>Experimental Function to Correct Confidence Intervals At or Near Boundaries of the Parameter Space by 'Sliding' the Interval on the Quantile Scale.</i>
------------	--

---

## Description

Experimental function to correct confidence intervals at or near boundaries of the parameter space by 'sliding' the interval on the quantile scale.

## Usage

```
ci.balance(x, est, confidence=0.95, alpha=1-confidence, minval, maxval,
           na.rm=TRUE)
```

## Arguments

x	Bootstrap parameter estimates.
est	Observed value of the parameter.
confidence	Confidence level for the interval. Defaults to 0.95.
alpha	Type I error rate (size) for the interval. Defaults to 1-confidence.
minval	A numeric value specifying the lower bound of the parameter space. Leave unspecified (the default) if there is no lower bound.
maxval	A numeric value specifying the upper bound of the parameter space. Leave unspecified (the default) if there is no upper bound.
na.rm	logical. Should missing values be removed?

## Details

### EXPERIMENTAL FUNCTION:

This function attempts to compute a proper `conf*100%` confidence interval for parameters at or near the boundary of the parameter space using bootstrapped parameter estimates by 'sliding' the confidence interval on the quantile scale.

This is accomplished by attempting to place a `conf *100%` interval symmetrically \*on the quantile scale\* about the observed value. If a symmetric interval would exceed the observed data at the upper (lower) end, a one-sided interval is computed with the upper (lower) boundary fixed at the the upper (lower) boundary of the parameter space.

**Value**

A list containing:

`ci` A 2-element vector containing the lower and upper confidence limits. The names of the elements of the vector give the actual quantile values used for the interval or one of the character strings "Upper Boundary" or "Lower Boundary".

`overflow.upper`, `overflow.lower`  
The number of elements beyond those observed that would be needed to compute a symmetric (on the quantile scale) confidence interval.

`n.above`, `n.below`  
The number of bootstrap values which are above (below) the observed value.

`lower.n`, `upper.n`  
The index of the value used for the endpoint of the confidence interval or the character string "Upper Boundary" ("Lower Boundary").

ci.balance(x,1, minval=0)
ci.balance(x,1)

x <- rnorm(100,1)
x <- ifelse(x>1, 1, x)
ci.balance(x,1, maxval=1)
ci.balance(x,1)
```

---

convert

*Efficiently convert strings of characters into integer codes*

---

**Description**

Efficiently convert strings of characters into integer codes.

**Usage**

```
convert(source, levels, byrow=FALSE, aslist=FALSE)
```

**Arguments**

<code>source</code>	Vector of character strings
<code>levels</code>	Vector of characters used to determine levels
<code>byrow</code>	Boolean. If FALSE (the default), return a matrix with one column per string. If TRUE, return a matrix with one row per string.
<code>aslist</code>	Boolean, return matrix (FALSE) or list of vectors (TRUE).

**Details**

This function efficiently converts character strings containing characters into vectors of integers. Its primary purpose is to allow translation of genotypes stored as character vectors, one character per genotype, to a factor-coded matrix. The equivalent code using `factor` is quite a bit slower, as shown by the last section of the example below.

The `levels` argument should be a vector of 1-character strings. This vector is used to determine the translation. The index of matching characters provides the returned integer values. Characters not present in `levels` will be converted to NA's.

**Value**

If `aslist=TRUE`, the return value is a list of vectors. Each vector will contain the translation of the corresponding input string.

If `aslist=FALSE` (the default), the return value will be a matrix. `byrow` controls whether each string is converted into a column (`byrow=FALSE`, the default) or row (`byrow=TRUE`).

When `byrow=FALSE`, each element of the `source` vector is converted to a column, and the number of rows will be the number of characters in the longest element of the `source` vector. Any shorter vectors will be padded with NA's.

When `byrow=TRUE` the matrix is created with one row per element of the `source` vector, etc.

**Note**

Only of the first character of each element of `levels` is used. Any other characters will be ignored.

```

**Description**

Converts integer codes in a callCodes matrix to character string representations of geneSet.

**Usage**

```
decodeCallCodes(callCodes, transTables, markerInfo)
```

**Arguments**

callCodes      matrix of positive integers, such as the callCodes slot of a geneSet object.  
transTables    list of code translation tables, such as the transTables slot of a geneSet object.  
markerInfo     dataframe, with one row for each row in the callCodes matrix, such as the markerInfo slot of a geneSet object. Must include at least column "TransTable".

**Value**

a character matrix with the same dimension and dimnames as argument callCodes, giving character string representations of genotypes, as specified by a set of translation tables.

**Author(s)**

Scott D. Chasalow

desMarkers

*Descriptive statistics for markers***Description**

Descriptive statistics for markers.

**Usage**

```
desMarkers (geneSetObj,
            founderOnly=TRUE,
            thrsh=0.05,
            HWE.method=c("simulate", "exact"),
            simulate.p.value=FALSE,
            B=10000,
            markerThrsh=100,
            maxDist=5,
            LDmeasure="r2",
            plot=TRUE,
            ...)
```

**Arguments**

geneSetObj	a geneSet object.
founderOnly	indicates if using only founder info
thrsh	threshold for Hardy-Weinberg equilibrium test. If the pvalue of the HWE test for a marker is greater than thrsh, then the marker is a good marker.
HWE.method	method to do Hardy-Weinberg equilibrium test.
simulate.p.value	indicates if the pvalue of the HWE test is calculated by Monte Carlo simulation. simulate.p.value=FALSE means the pvalue is calculated from asymptotic chi-squared distribution of the test statistic. Otherwise, Monte Carlo simulation is used to calculate pvalue. For more details, please refers to the R function chisq.test.
B	the number of replicates used in Monte Carlo simulation to get the pvalue of HWE test. For more details, please refers to the R function chisq.test.
markerThrsh	if the number of markers is greater than this threshold, then 'LDdist' is called instead of 'LD'.
maxDist	the width of window used in 'LDdist' function.
LDmeasure	indicates if $r^2$ or $D'$ is to be plot.
plot	indicates if LD plot is output or not.
...	Other arguments that are used by HWE.chisq or HWE.exact.

**Value**

a data frame contains components:

Name	marker names
------	--------------

Position	marker positions
ObsHET	marker's observed heterozygosity (i.e., proportion of heterozygotes at marker). Missing alleles are excluded in the calculation.
PredHET	marker's predicted heterozygosity (i.e., $2 * \text{MAF} * (1 - \text{MAF})$ ). Missing alleles are excluded in the calculation.
HWpval	pvalues for Hardy-Weinberg test
pGeno	percentage of non-missing genotypes for marker
MAF	minor allele frequencies. missing allele are excluded from calculation
Rating	Rating[i]=1 means that the <i>i</i> -th marker passes HW test (do not reject H0 that HW equilibrium holds). Rating[i]=0 means HW equilibrium does hold for the <i>i</i> -th marker.

**Examples**

```
#data (CAMP)
#res<-desMarkers (CAMP)
#print (res)
```

---

diseq	<i>Estimate or Compute Confidence Interval for the Single-Marker Disequilibrium</i>
-------	---

---

**Description**

Estimate or compute confidence interval for single-marker disequilibrium.

**Usage**

```
diseq.ci(object, marker, R = 1000, conf = 0.95, correct = TRUE, na.rm =
TRUE, ...)
diseq.inner(object, marker, ...)
```

**Arguments**

object	geneSet object
marker	marker names
R	Number of bootstrap iterations to use when computing the confidence interval. Defaults to 1000.
conf	Confidence level to use when computing the confidence level for D-hat. Defaults to 0.95, should be in (0,1).
correct	See details.
na.rm	logical. Should missing values be removed?
...	optional additional parameters passed

## Details

For a single-gene marker, `diseq` computes the Hardy-Weinberg (dis)equilibrium statistic  $D$ ,  $D'$ ,  $r$  (the correlation coefficient), and  $r^2$  for each pair of allele values, as well as an overall summary value for each measure across all alleles. `print.diseq` displays the contents of a `diseq` object. `diseq.ci` computes a bootstrap confidence interval for this estimate.

For consistency, I have applied the standard definitions for  $D$ ,  $D'$ , and  $r$  from the Linkage Disequilibrium case, replacing all marker probabilities with the appropriate allele probabilities.

Thus, for each allele pair,

$D$  is defined as the half of the raw difference in frequency between the observed number of heterozygotes and the expected number:

$$D = \frac{1}{2}(p_{ij} + p_{ji}) - p_i p_j$$

$D'$  rescales  $D$  to span the range [-1,1]

$$D' = \frac{D}{D_{max}}$$

where, if  $D > 0$ :

$$D_{max} = \min p_i p_j, p_j p_i = p_i p_j$$

or if  $D < 0$ :

$$D_{max} = \min p_i(1 - p_j), p_j(1 - p_i)$$

$r$  is the correlation coefficient between two alleles, and can be computed by

$$r = \frac{-D}{\sqrt{(p_i * (1 - p_i) p(j)(1 - p_j))}}$$

where

- $p_i$  defined as the observed probability of allele 'i',
- $p_j$  defined as the observed probability of allele 'j', and
- $p_{ij}$  defined as the observed probability of the allele pair 'ij'.

When there are more than two alleles, the summary values for these statistics are obtained by computing a weighted average of the absolute value of each allele pair, where the weight is determined by the expected frequency. For example:

$$D_{overall} = \sum_{i \neq j} |D_{ij}| * p_{ij}$$

Bootstrapping is used to generate confidence interval in order to avoid reliance on parametric assumptions, which will not hold for alleles with low frequencies (e.g.  $D'$  following a Chi-square distribution).

See the function `HWE` from "genetics" package for testing Hardy-Weinberg Equilibrium,  $D = 0$ .

extractAlleles      *functions for extracting allele levels, allele pairs, and allele codes*

---

### Description

functions for extracting allele levels, allele pairs, and allele codes

### Usage

```
extractAlleles(object, which = c(1, 2), codes = FALSE,
allow.partial.missing = FALSE, marker, obs)
```

### Arguments

object	geneSet object
which	allele pair number - 1 or 2. Default if both
codes	If FALSE (default), then alleles are shown as characters, else numeric
allow.partial.missing	Whether partial matching should be allowed ( default is FALSE)
marker	marker names
obs	Number of observations (samples) to be displayed. Default is all.

---

fastGrid      *Create a matrix giving all combinations of the elements of x*

---

### Description

Create a matrix giving all combinations of the elements of x

### Usage

```
fastGrid(x)
```

### Arguments

x	a vector
---	----------

### Value

a matrix of the same mode as x, with dimension  $c(\text{length}(x), 2)$ . The rows give all points on a square lattice formed by pairing every element of x with every element of x. Here, order matters - that is, (1, 2) and (2, 1) both would be included - and points with an element taken twice - e.g. (1, 1) - also are included.

data(CAMP)
founders<-founderGeneSet(CAMP)
```

---

geneSet2Ped      *Translate a geneSet object to a ped matrix*

---

**Description**

Translate a geneSet object to a ped matrix.

**Usage**

```
geneSet2Ped(geneSetObj)
```

**Arguments**

geneSetObj      an object of geneSet class

**Value**

A list with five elements: `ped`, `columns`, `markerNames`, `Position`, and `fileName`. `ped` is a pedigree data frame whose first 6 columns are family (pedigree id), pid (patient id), father (father id), mother (mother id), sex, affected (affection status). The remaining columns are pairs of marker alleles. Each row corresponds to an individual; `columns` are the names of the first 5 (or 6) columns of `ped` file. It should be either equal to `c("family","pid","father","mother","sex","affected")` or equal to `c("family","pid","father","mother","sex")`; `founderOnly` indicates if using only founder info; `markerNames` is a vector of marker names; `Position` is a vector of marker positions; `fileName` is the pedigree file name.

```
data(CAMP)
res<-geneSet2Ped(CAMP)
res$ped[1:5,]
res$columns
res$markerNames
res$Position
res$fileName
```

---

geneSet-class

*Class "geneSet", a class for genetics data*

---

**Description**

A fundamental data structure for genetic data

**Objects from the Class**

Objects can be created by calls of the form `new("geneSet", ...)`. ~~~ describe objects here  
~~~

**Slots**

**callCodes:** matrix of positive integers, giving genotype calls. Each row is a locus (marker); each column is an individual (sample). Each element is a row index into a matrix in the list of translation tables stored in the `transTables` slot. Must have row and column names.

**errorMetrics:** numeric matrix, parallel to the `callCodes` matrix. Each element gives an uncertainty measure for the corresponding element of the `callCodes` matrix. Must have row and column names.

**transTables:** list of code translation tables. The list must have names. Each component is a matrix, and must include a column named "levels".

**missingCodes:** list of allele missing-value codes, parallel to the transTables list. The list must have the same names as the list in the transTables slot. Each component is a character vector. Any allele symbol in component "abc" of the transTables list that appears in component "abc" of the missingCodes list is to be interpreted as a missing value by functions operating on the geneSet object. An empty list will be interpreted to mean that the data contains no missing values.

**sampleInfo:** Object of class "data.frame"

**markerInfo:** a dataframe, with one row for each row in the callCodes matrix. Must include columns "Name" and "TransTable".

**studyInfo:** Object of class "list" ~~

**description:** Object of class "character" ~~

**notes:** Object of class "character" ~~

**ploidy:** Object of class "numeric" ~~

**phase:** 1. Yes/No for all (logical scalar) 2. Yes/No for each Marker (logical vector) 3. phaseObject (TBD): observation by marker by phase probabilities + definitions of contigs + probability of contigs

genotypeCoding      *Get genotype coding*

---

**Description**

Get genotype coding.

**Usage**

```
genotypeCoding(geneSetObj, method = "A")
genotypeCoding.default(pedObj, method = "A")
```

**Arguments**

geneSetObj      a geneSet object  
 pedObj          a pedigree object  
 method          genotype coding method. The default is additive coding (A). The other two available coding methods are recessive coding (R) and dominant coding (D), respectively.

**Value**

a matrix with nSubjects rows and nMarkers columns. Each column contains coded genotype.

| omitRepeats      | logical value (TRUE/FALSE) indicating whether Gene name and marker name should be printed repeatedly for each Genotype, default = TRUE |
| founderOnly      | logical value (TRUE/FALSE) indicating whether founder information should be extracted from the geneSet object, default = FALSE         |
| ...              | any further arguments to print                                                                                                         |

**Details**

We can print the genotypeSummary on screen, or save in .html format or .tex format

**Author(s)**

Nitin Jain (nitin.jain@pfizer.com)

**Examples**

```
library(GeneticsBase)
data(CAMP)

temp <- genotypeSummary(CAMP)

print(temp)
txt(temp, filename="genotypeSummary.txt")
html(temp, filename="genotypeSummary.html")
latex(temp, filename="genotypeSummary.tex")
```

|           |                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------|
| gregorius | <i>Probability of Observing All Alleles with a Given Frequency in a Sample of a Specified Size.</i> |
|-----------|-----------------------------------------------------------------------------------------------------|

---

**Description**

Probability of observing all alleles with a given frequency in a sample of a specified size.

**Usage**

```
gregorius(freq, N, missprob, tol = 1e-10, maxN = 10000, maxiter=100, showiter =
```

**Arguments**

|          |                                                                                        |
|----------|----------------------------------------------------------------------------------------|
| freq     | (Minimum) Allele frequency (required)                                                  |
| N        | Number of sampled genotypes                                                            |
| missprob | Desired maximum probability of failing to observe an allele.                           |
| tol      | Omit computation for terms which contribute less than this value.                      |
| maxN     | Largest value to consider when searching for N.                                        |
| maxiter  | Maximum number of iterations to use when searching for N.                              |
| showiter | Boolean flag indicating whether to show the iterations performed when searching for N. |

**Details**

If `freq` and `N` are provided, but `missprob` is omitted, this function computes the probability of failing to observe all alleles with true underlying frequency `freq` when `N` diploid genotypes are sampled. This is accomplished using the sum provided in Corollary 2 of Gregorius (1980), omitting terms which contribute less than `tol` to the result.

When `freq` and `missprob` are provide, but `N` is omitted. A binary search on the range of `[1,maxN]` is performed to locate the smallest sample size, `N`, for which the probability of failing to observe all alleles with true underlying frequency `freq` is at most `missprob`. In this case, `maxiter` specifies the largest number of iterations to use in the binary search, and `showiter` controls whether the iterations of the search are displayed.

**Value**

A list containing the following values:

|                               |                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>             | Function call used to generate this object.                                                                                                                    |
| <code>method</code>           | One of the strings, "Compute missprob given N and freq", or "Determine minimal N given missprob and freq", indicating which type of computation was performed. |
| <code>retval\$freq</code>     | Specified allele frequency.                                                                                                                                    |
| <code>retval\$N</code>        | Specified or computed sample size.                                                                                                                             |
| <code>retval\$missprob</code> | Computed probability of failing to observe all of the alleles with frequency <code>freq</code> .                                                               |

**Note**

This code produces sample sizes that are slightly larger than those given in table 1 of Gregorius (1980). This appears to be due to rounding of the computed `missprobs` by the authors of that paper.

**Author(s)**

Code submitted by David Duffy <davidD@qumr.edu.au>, substantially enhanced by Gregory R. Warnes <warnes@bst.rochester.edu>.

**References**

Gregorius, H.R. 1980. The probability of losing an allele when diploid genotypes are sampled. *Biometrics* 36, 643-652.

**Examples**

```
# Compute the probability of missing an allele with frequency 0.15 when
# 20 genotypes are sampled:
gregorius(freq=0.15, N=20)

# Determine what sample size is required to observe all alleles with true
# frequency 0.15 with probability 0.95
gregorius(freq=0.15, missprob=1-0.95)
```

---

haplo.em.w

---

*Wrapper for EM computation of haplotype probabilities, with Progressive Insertion*

---

**Description**

Wrapper for EM computation of haplotype probabilities, with Progressive Insertion.

**Usage**

```
haplo.em.w(geneSetObj,
           locus.label = NA,
           miss.val = c(0, NA),
           weight = NULL,
           control = haplo.em.control())
```

**Arguments**

|             |                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------|
| geneSetObj  | a geneSet object.                                                                                      |
| locus.label | vector of labels for loci.                                                                             |
| miss.val    | vector of values that represent missing alleles in geno.                                               |
| weight      | weights for observations.                                                                              |
| control     | list of control parameters. The default is constructed by the function <code>haplo.em.control</code> . |

**Details**

Please refer to [haplo.em](#) for more details.

**Value**

list with components:

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| converge    | indicator of convergence of the EM algorithm (1 = converge, 0 = failed).                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| lnlike      | value of lnlike at last EM iteration (maximum lnlike if converged).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| lr          | likelihood ratio statistic to test the final lnlike against the lnlike that assumes complete linkage equilibrium among all loci (i.e., haplotype frequencies are products of allele frequencies).                                                                                                                                                                                                                                                                                                                                                    |
| df.lr       | degrees of freedom for likelihood ratio statistic. The df for the unconstrained final model is the number of non-zero haplotype frequencies minus 1, and the df for the null model of complete linkage equilibrium is the sum, over all loci, of (number of alleles - 1). The df for the lr statistic is df[unconstrained] - df>null]. This can result in negative df, if many haplotypes are estimated to have zero frequency, or if a large amount of trimming occurs, when using large values of min.posterior in the list of control parameters. |
| hap.prob    | vector of mle's of haplotype probabilities. The ith element of hap.prob corresponds to the ith row of haplotype.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| locus.label | vector of labels for loci, of length K (see definition of input values).                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| subj.id     | vector of id's for subjects used in the analysis, based on row number of input geno matrix. If subjects are removed, then their id will be missing from subj.id.                                                                                                                                                                                                                                                                                                                                                                                     |
| rows.rem    | now defunct, but set equal to a vector of length 0, to be compatible with other functions that check for rows.rem.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| indx.subj   | vector for row index of subjects after expanding to all possible pairs of haplotypes for each person. If indx.subj=i, then i is the ith row of geno. If the ith subject has n possible pairs of haplotypes that correspond to their marker genotype, then i is repeated n times.                                                                                                                                                                                                                                                                     |
| nreps       | vector for the count of haplotype pairs that map to each subject's marker genotypes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|           |                                                                                                                                                                                                               |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max.pairs | vector of maximum number of pairs of haplotypes per subject that are consistent with their marker data in the matrix geno. The length of max.pairs = nrow(geno). This vector is computed by geno.count.pairs. |
| hap1code  | vector of codes for each subject's first haplotype. The values in hap1code are the row numbers of the unique haplotypes in the returned matrix haplotype.                                                     |
| hap2code  | similar to hap1code, but for each subject's second haplotype.                                                                                                                                                 |
| post      | vector of posterior probabilities of pairs of haplotypes for a person, given their marker phenotypes.                                                                                                         |
| haplotype | matrix of unique haplotypes. Each row represents a unique haplotype, and the number of columns is the number of loci.                                                                                         |
| control   | list of control parameters for algorithm. See haplo.em.control                                                                                                                                                |

| haplo.scan.w | <i>Wrapper for searching for a trait-locus by sliding a fixed-width window over each marker locus and scanning all possible haplotype lengths within the window</i> |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

---

**Description**

Wrapper for searching for a trait-locus by sliding a fixed-width window over each marker locus and scanning all possible haplotype lengths within the window.

**Usage**

```
haplo.scan.w(geneSetObj,
             width = 4,
             miss.val = c(0, NA),
             em.control = haplo.em.control(),
             sim.control = score.sim.control())
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| geneSetObj  | A geneSet object                                                                                                                                                                                                                                                                          |
| width       | Width of sliding the window                                                                                                                                                                                                                                                               |
| miss.val    | Vector of values that represent missing alleles in geno.                                                                                                                                                                                                                                  |
| em.control  | A list of control parameters to determine how to perform the EM algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function <a href="#">haplo.em.control</a> - see this function for more details.                                          |
| sim.control | List of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function <a href="#">score.sim.control</a> and the default values of this function can be changed as desired. See <a href="#">score.sim.control</a> for details. |

**Details**

Please refer to [haplo.scan](#) for more details.

**Value**

A list that has class haplo.scan, which contains the following items:

|         |                                                                                                                   |
|---------|-------------------------------------------------------------------------------------------------------------------|
| call    | The call to haplo.scan.w                                                                                          |
| scan.df | A data frame containing the maximum test statistic for each window around each locus, and its simulated p-value.  |
| max.loc | The loci (locus) which contain(s) the maximum observed test statistic over all haplotype lengths and all windows. |
| globalp | A p-value for the significance of the global maximum statistic.                                                   |
| nsim    | Number of simulations performed                                                                                   |

```

---

```
haplo.score.slide.w
```

*Wrapper for haplo.score.slide in haplo.stats package, which is used to identify sub-haplotypes from a group of loci*

---

**Description**

Wrapper for `haplo.score.slide`, which is used to identify sub-haplotypes from a group of loci. Run `haplo.score` on all contiguous subsets of size `n.slide` from the loci in a genotype matrix (`geno`). From each call to `haplo.score`, report the global score statistic p-value. Can also report global and maximum score statistics simulated p-values.

**Usage**

```
haplo.score.slide.w(geneSetObj,
                    trait.type = "gaussian",
                    n.slide = 2,
                    offset = NA,
                    x.adj = NA,
                    skip.haplo = 5/(2 * nrow(geno)),
                    locus.label = NA,
                    miss.val = c(0, NA),
                    simulate = FALSE,
                    sim.control = score.sim.control(),
                    em.control = haplo.em.control())
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>geneSetObj</code>  | A <code>geneSet</code> object                                                                                                                                                                                                                                                                                                  |
| <code>trait.type</code>  | Character string defining type of trait, with values of “gaussian”, “binomial”, “poisson”, “ordinal”.                                                                                                                                                                                                                          |
| <code>n.slide</code>     | Number of loci in each contiguous subset. The first subset is the ordered loci numbered 1 to <code>n.slide</code> , the second subset is 2 through <code>n.slide+1</code> and so on. If the total number of loci in <code>geno</code> is <code>n.loci</code> , then there are <code>n.loci - n.slide + 1</code> total subsets. |
| <code>offset</code>      | Vector of offset when <code>trait.type</code> = “poisson”                                                                                                                                                                                                                                                                      |
| <code>x.adj</code>       | Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should not be included, as it will be added in this function.                                                                                                                                                                        |
| <code>skip.haplo</code>  | Skip score statistics for haplotypes with frequencies < <code>skip.haplo</code> . The default is for an expected count of 5 out of the $2^N$ haplotype occurrences.                                                                                                                                                            |
| <code>locus.label</code> | Vector of labels for loci.                                                                                                                                                                                                                                                                                                     |

|                          |                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>miss.val</code>    | Vector of values that represent missing alleles in geno.                                                                                                                                                                                                                            |
| <code>simulate</code>    | Logical: if [F]alse, no empirical p-values are computed; if [T]rue, simulations are performed. Specific simulation parameters can be controlled in the <code>sim.control</code> parameter list.                                                                                     |
| <code>sim.control</code> | list of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function <code>score.sim.control</code> and the default values of this function can be changed as desired. See <code>score.sim.control</code> for details. |
| <code>em.control</code>  | A list of control parameters to determine how to perform the EM algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function <code>haplo.em.control</code> - see this function for more details                                        |

### Details

Please refer to `haplo.score.slide` for more details.

### Value

List with the following components:

|                           |                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>df</code>           | Data frame with start locus, global p-value, simulated global p-value, and simulated maximum-score p-value.                                                                                                                                                                                              |
| <code>n.loci</code>       | Number of loci given in the genotype matrix.                                                                                                                                                                                                                                                             |
| <code>simulate</code>     | Same as parameter description above.                                                                                                                                                                                                                                                                     |
| <code>n.slide</code>      | Same as parameter description above.                                                                                                                                                                                                                                                                     |
| <code>locus.label</code>  | Same as parameter description above.                                                                                                                                                                                                                                                                     |
| <code>n.val.haplo</code>  | Vector containing the number of valid simulations used in the maximum-score statistic p-value simulation. The number of valid simulations can be less than the number of simulations requested (by <code>sim.control</code> ) if simulated data sets produce unstable variables of the score statistics. |
| <code>n.val.global</code> | Vector containing the number of valid simulations used in the global score statistic p-value simulation.                                                                                                                                                                                                 |

| haplo.score.w | <i>Wrapper for computing score statistics to evaluate the association of a trait with haplotypes, when linkage phase is unknown and diploid marker phenotypes are observed among unrelated subjects</i> |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

---

**Description**

wrapper for computing score statistics to evaluate the association of a trait with haplotypes, when linkage phase is unknown and diploid marker phenotypes are observed among unrelated subjects. For now, only autosomal loci are considered.

**Usage**

```
haplo.score.w(geneSetObj,
              trait.type = "gaussian",
              offset = NA,
              x.adj = NA,
              skip.haplo = 5/(2 * nrow(geno)),
              locus.label = NA,
              miss.val = c(0, NA),
              simulate = FALSE,
              sim.control = score.sim.control(),
              em.control = haplo.em.control())
```

**Arguments**

|             |                                                                                                                                                                                    |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| geneSetObj  | A geneSet object                                                                                                                                                                   |
| trait.type  | Character string defining type of trait, with values of “gaussian”, “binomial”, “poisson”, “ordinal”.                                                                              |
| offset      | Vector of offset when trait.type = “poisson”                                                                                                                                       |
| x.adj       | Matrix of non-genetic covariates used to adjust the score statistics. Note that intercept should not be included, as it will be added in this function.                            |
| skip.haplo  | Skip score statistics for haplotypes with frequencies < skip.haplo. The default is for an expected count of 5 out of the 2*N haplotype occurrences.                                |
| locus.label | Vector of labels for loci.                                                                                                                                                         |
| miss.val    | vector of values that represent missing alleles in geno.                                                                                                                           |
| simulate    | Logical: if [F]alse, no empirical p-values are computed; if [T]rue, simulations are performed. Specific simulation parameters can be controlled in the sim.control parameter list. |

|                          |                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sim.control</code> | List of control parameters to determine how simulations are performed for simulated p-values. The list is created by the function <code>score.sim.control</code> and the default values of this function can be changed as desired. See <code>score.sim.control</code> for details. |
| <code>em.control</code>  | A list of control parameters to determine how to perform the EM algorithm for estimating haplotype frequencies when phase is unknown. The list is created by the function <code>haplo.em.control</code> - see this function for more details                                        |

## Details

Please refer to [haplo.score](#) for more details.

## Value

List with the following components:

|                                 |                                                                                                                                                                                                                                                                                                 |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>score.global</code>       | Global statistic to test association of trait with haplotypes that have frequencies $\geq$ <code>skip.haplo</code> .                                                                                                                                                                            |
| <code>df</code>                 | Degrees of freedom for <code>score.global</code> .                                                                                                                                                                                                                                              |
| <code>score.global.p</code>     | P-value of <code>score.global</code> based on chi-square distribution, with degrees of freedom equal to <code>df</code> .                                                                                                                                                                       |
| <code>score.global.p.sim</code> | P-value of <code>score.global</code> based on simulations (set equal to NA when <code>simulate=F</code> ).                                                                                                                                                                                      |
| <code>score.haplo</code>        | Vector of score statistics for individual haplotypes that have frequencies $\geq$ <code>skip.haplo</code> .                                                                                                                                                                                     |
| <code>score.haplo.p</code>      | Vector of p-values for <code>score.haplo</code> , based on a chi-square distribution with 1 df.                                                                                                                                                                                                 |
| <code>score.haplo.p.sim</code>  | Vector of p-values for <code>score.haplo</code> , based on simulations (set equal to NA when <code>simulate=F</code> ).                                                                                                                                                                         |
| <code>score.max.p.sim</code>    | Simulated p-value indicating for simulations the number of times a maximum <code>score.haplo</code> value exceeds the maximum <code>score.haplo</code> from the original data (equal to NA when <code>simulate=F</code> ).                                                                      |
| <code>haplotype</code>          | Matrix of haplotypes analyzed. The <i>i</i> th row of <code>haplotype</code> corresponds to the <i>i</i> th item of <code>score.haplo</code> , <code>score.haplo.p</code> , and <code>score.haplo.p.sim</code> .                                                                                |
| <code>hap.prob</code>           | Vector of haplotype probabilities, corresponding to the haplotypes in the matrix <code>haplotype</code> .                                                                                                                                                                                       |
| <code>locus.label</code>        | Vector of labels for loci, of length <i>K</i> (same as input argument).                                                                                                                                                                                                                         |
| <code>simulate</code>           | Same as function input parameter. If [T]rue, simulation results are included in the <code>haplo.score</code> object.                                                                                                                                                                            |
| <code>n.val.global</code>       | Vector containing the number of valid simulations used in the global score statistic simulation. The number of valid simulations can be less than the number of simulations requested (by <code>sim.control</code> ) if simulated data sets produce unstable variances of the score statistics. |
| <code>n.val.haplo</code>        | Vector containing the number of valid simulations used in the p-value simulations for maximum-score statistic and scores for the individual haplotypes.                                                                                                                                         |

hapmapchr22

*Chromosome 22 genotypes from International HapMap project*

---

**Description**

The sample data file, hapmapchr22, contains genotypes of hromosome 22 from the International HapMap project. This file contains genotypes from 30 CEPH trios (90 subjects) for all Phase 1 HapMap (about 1 SNP per 3kb on average) - see <http://hapmap.org> for the original data file, full details of samples, markers and methods. Note that the HapMap data files are deidentified and freely distributable without restriction.

**Usage**

```
data(hapmapchr22)
```

**Format**

The format is: chr "hapmapchr22"

**Details**

The file was created by converting chromosome 22 bulk data download data files from the HapMap file repository at [http://hapmap.org/genotypes/2005-06\\_16c\\_phaseI/full/non-redundant/](http://hapmap.org/genotypes/2005-06_16c_phaseI/full/non-redundant/)

Downloaded HapMap files were converted by transposing the layout of the data from one row per marker to the pedigree file convention of two columns per marker. There are many variants of the pedigree format but these files are compatible with the popular family based analysis software packages FBAT (<http://www.biostat.harvard.edu/~fbat/fbat.htm>) and PBAT (<http://www.biostat.harvard.edu/~clang/default.htm>)

The file has a header row containing only the marker names followed by one row per subject. Data rows always start with 6 fields - family\_id, individual\_id, father\_id, mother\_id, gender and affection status. Parents have zero for mother\_id and father\_id. The remaining

columns in each row contain two allele codes for each marker. Alleles are coded as 0 for missing, 1 = A, 2 = C, 3 = G and 4 = T. All fields in a row are delimited by one or more spaces. Note that affection status was arbitrarily set to 2 (affected) for children and 1 (unaffected) for adults - although in reality, HapMap CEPH subjects were not ascertained for any disease.

### Examples

```
data(hapmapchr22)
```

---

homozygote

*Flag observations with specific allele patterns*

---

### Description

**homozygote** Flag observations with identical alleles

**heterozygote** Flag observations with discordant alleles

**carrier** Flag observations containing a specified allele

**dominant** Flag observations containing one or more of the specified alleles.

**recessive** Flag observations containing only the specified alleles.

### Usage

```
homozygote(object, ...)
```

```
homozygote.geneSet(object, allele.names, marker, ...)
```

```
heterozygote(object, ...)
```

```
heterozygote.geneSet(object, allele.names, marker, ...)
```

```
carrier(object, ...)
```

```
carrier.geneSet(object, allele.names, marker, ...)
```

```
dominant(object, ...)
```

```
dominant.geneSet(object, allele.names, marker, ...)
```

```
recessive(object, ...)
```

```
recessive.geneSet(object, allele.names, marker, ...)
```

**Arguments**

object            geneSet object  
allele.names    (optional) allele names.  
marker           (optional) marker names  
...              (optional) additional arguments supplied

**Value**

matrix of logicals.

html

*Generate summary table files for genotype objects*

---

**Description**

Generate summary table files for genotype objects

**Usage**

```
##### HTML file format
html
## S3 method for class 'LD':
html(x, filename = "", digits = 3, ...)
## S3 method for class 'GeneticsBaseSummary':
html(x, filename = "", ...)
## S3 method for class 'markerSummary':
html(x, filename = "", plot.format = "pdf",
      sep=".", verbose=TRUE, ...)

##### plain text file format
txt
## Default S3 method:
txt(x, filename="", eol="\n", ...)
## S3 method for class 'markerSummary':
txt(x, filename = "", plot.format = "pdf",
     sep=".", verbose=TRUE, ...)

##### LaTeX file format
latex
## Default S3 method:
latex(x, filename="", ...)
## S3 method for class 'LD':
latex(x, filename = "", digits = 3, ...)
## S3 method for class 'GeneticsBaseSummary':
latex(x, filename = "", ...)
## S3 method for class 'markerSummary':
latex(x, filename = "", plot.format = "pdf",
      sep=".", verbose=TRUE, ...)
```

**Arguments**

|             |                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------|
| x           | Object to be rendered to html/txt/latex                                                                     |
| filename    | Output filename, see below for details.                                                                     |
| eol         | End of line marker, defaults to "\n". MS-DOS/MS-Windows uses "\r\n"                                         |
| digits      | Number of digits to display                                                                                 |
| plot.format | Graphics format for LD plot. Only "pdf" is currently supported                                              |
| sep         | Separator used to join the file prefix provided by filename and descriptive text when generating file names |
| verbose     | Show names of created files.                                                                                |
| ...         | Additional parameters to pass to component methods                                                          |

**Details**

For `alleleSummary`, `genotypeSummary`, and `LD` objects, the `filename` argument is either the exact name of the file to be created, or "" which will print the output to the console.

For `markerSummary` objects, `filename` may be either "" or a prefix used to create file names. If `filename=""` all output is printed to the R console. Otherwise, filenames for each component

are constructed by combining the prefix specified by `filename`, the separator specified by `sep`, a string describing the file contents (one of "alleleSummary", "genotypeSummary", and "LD"), and the file extension ".html".

---

`HWE.chisq`*Hardy-Weinberg Equilibrium Significance test for a biallelic locus*

---

### Description

Hardy-Weinberg Equilibrium Significance test for a biallelic locus .

### Usage

```
HWE.chisq(object,  
          marker,  
          simulate.p.value = TRUE,  
          B = 10000,  
          founderOnly=TRUE,  
          ...)
```

### Arguments

|                               |                                                                                                 |
|-------------------------------|-------------------------------------------------------------------------------------------------|
| <code>object</code>           | a <code>geneSet</code> object.                                                                  |
| <code>marker</code>           | marker name for the biallelic locus.                                                            |
| <code>simulate.p.value</code> | a logical indicating whether to compute p-values by Monte Carlo simulation.                     |
| <code>B</code>                | an integer specifying the number of replicates used in the Monte Carlo test. Defaults to 10000. |
| <code>founderOnly</code>      | Indicates if only founders are used to do the test.                                             |
| <code>...</code>              | Other arguments used by the function <code>chisq.test</code> .                                  |

### Value

The values of the function `HWE.chisq` is the same as those of the function `chisq.test`. Part of the values are listed below:

|                        |                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>statistic</code> | the value the chi-squared test statistic.                                                                                                            |
| <code>parameter</code> | the degrees of freedom of the approximate chi-squared distribution of the test statistic, 'NA' if the p-value is computed by Monte Carlo simulation. |
| <code>p.value</code>   | the p-value for the test.                                                                                                                            |

```
library(GeneticsBase)
data(CAMP)

HWE.chisq(CAMP, marker="m654")
```

---

HWE.exact

*Exact test for Hardy-Weinberg Equilibrium for a biallelic locus*

---

**Description**

Exact test for Hardy-Weinberg Equilibrium for a biallelic locus.

**Usage**

```
HWE.exact(object,
           marker,
           founderOnly=TRUE)
```

**Arguments**

|             |                                                     |
|-------------|-----------------------------------------------------|
| object      | a geneSet object.                                   |
| marker      | marker name for the biallelic locus.                |
| founderOnly | Indicates if only founders are used to do the test. |

**Value**

The function HWE returns a list with class `hctest` containing the following elements:

|           |                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------|
| statistic | A 3-element vector records the genotype frequencies: N11, N12, N22.                                         |
| parameter | A 2-element vector records the allele frequencies: N1 and N2                                                |
| p.value   | p-value of the test.                                                                                        |
| method    | Information indicates if <code>chisquare</code> method or <code>exact</code> method is used to do HWE test. |
| data.name | name of the data set                                                                                        |
| observed  | a table lists allele levels, allele pairs, and allele codes                                                 |

**Note**

This function only works for genotypes with exactly 2 alleles.

HWE

*Test the significances of Hardy-Weinberg Equilibrium (dis)equilibrium statistics*

---

**Description**

Test the significances of Hardy-Weinberg Equilibrium (dis)equilibrium statistics for each marker in a data set.

**Usage**

```
HWE(object,
     test = c("exact", "permutation", "chisq"),
     B = 10000,
     R = 1000,
     correct = TRUE,
     conf = c(0.95),
     na.rm = TRUE,
     founderOnly = TRUE,
     ...)
```

**Arguments**

|                          |                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | a <code>geneSet</code> object.                                                                                                         |
| <code>test</code>        | specifys the test method. Available methods are “exact”, “permutation”, “chisq”.                                                       |
| <code>B</code>           | an integer specifying the number of replicates used in the Monte Carlo test. Defaults to 10000.                                        |
| <code>R</code>           | Number of bootstrap iterations to use when computing the confidence interval. Defaults to 1000.                                        |
| <code>correct</code>     | see <a href="#">diseq.ci</a> .                                                                                                         |
| <code>conf</code>        | Confidence level to use when computing the confidence level for linkage disequilibrium measures. Defaults to 0.95, should be in (0,1). |
| <code>na.rm</code>       | logical. Should missing values be removed?                                                                                             |
| <code>founderOnly</code> | Indicates if only founders are used to do the test.                                                                                    |
| <code>...</code>         | othere arguments used by the function <a href="#">chisq.test</a> .                                                                     |

**Value**

The function HWE returns a list:

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\dQuote{diseq}</code>   | a character string.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>call</code>             | the matched call.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>\dQuote{D}</code>       | a matrix with $m$ rows and $3 + p$ columns, where $m$ is the number of markers in the <code>geneSet</code> , $p$ is the number of elements of the argument <code>conf</code> . The first column is the estimated “D”. The next $p$ columns are estimated confidence limits for the confidence levels specified in the argument <code>conf</code> . The last two columns are the sample size and the p-value of the test that “D” is equal to zero.   |
| <code>\dQuote{D'}</code>      | a matrix with $m$ rows and $3 + p$ columns, where $m$ is the number of markers in the <code>geneSet</code> , $p$ is the number of elements of the argument <code>conf</code> . The first column is the estimated “D’”. The next $p$ columns are estimated confidence limits for the confidence levels specified in the argument <code>conf</code> . The last two columns are the sample size and the p-value of the test that “D’” is equal to zero. |
| <code>\dQuote{r}</code>       | a matrix with $m$ rows and $3 + p$ columns, where $m$ is the number of markers in the <code>geneSet</code> , $p$ is the number of elements of the argument <code>conf</code> . The first column is the estimated “r”. The next $p$ columns are estimated confidence limits for the confidence levels specified in the argument <code>conf</code> . The last two columns are the sample size and the p-value of the test that “r” is equal to zero.   |
| <code>\dQuote{X\$^2\$}</code> | a matrix with $m$ rows and $3 + p$ columns, where $m$ is the number of markers in the <code>geneSet</code> , $p$ is the number of elements of the argument <code>conf</code> . The first column is the test statistic “X <sup>2</sup> ” for HWE test. The next $p$ columns are zeros. The last two columns are the sample size and the p-value of the test for Hardy-Weinberg equilibrium.                                                           |

 LD

---

*Pairwise linkage disequilibrium between genetic markers.*

---

**Description**

Compute pairwise linkage disequilibrium between genetic markers

**Usage**

```
LD(object, pooling.threshold = 0.1, founderOnly = FALSE, quiet = TRUE )
LDband(object, width=31, pooling.threshold=0.1, founderOnly=FALSE, quiet=TRUE)
LDband.geneSet(object, width=31, pooling.threshold=0.1, founderOnly=FALSE, quiet=TRUE)
LDdist.geneSet(object, posVec, maxDist, pooling.threshold=0.1, founderOnly=FALSE, quiet=TRUE)

summary.LD(object,
            which = c("D", "D'", "r", "R^2", "X^2", "P-value", "LOD", "n"),
            rowsep,
            digits = 3, ...)
```

**Arguments**

|                                |                                                                   |
|--------------------------------|-------------------------------------------------------------------|
| <code>object</code>            | geneSet object                                                    |
| <code>width</code>             | window width                                                      |
| <code>posVec</code>            | marker position                                                   |
| <code>maxDist</code>           | size of the window based on distance                              |
| <code>pooling.threshold</code> | Threshold for LD calculation                                      |
| <code>which</code>             | character string indicates which LD statistic should be print out |
| <code>rowsep</code>            | separator for rows                                                |
| <code>digits</code>            | the desired number of digits after the decimal point              |
| <code>founderOnly</code>       | Indicates if only founders are used to do the test.               |
| <code>quiet</code>             | Indicates if intermediate results should be output                |
| <code>...</code>               | additional optional arguments                                     |

**Details**

Linkage disequilibrium (LD) is the non-random association of marker alleles and can arise from marker proximity or from selection bias.

LD estimates the extent of LD for all pairs of genotypes contained in a `object`. `LDband` computes the extent of LD of markers within a window containing `width` markers centered around each marker in `object`.

The current (temporary) code only computes LD for markers with exactly 2 variants. For other markers, NA is returned.

Three estimators of LD are computed:

D raw difference in frequency between the observed number of AB pairs and the expected number:

$$D = p_{AB} - p_A p_B$$

D' scaled D spanning the range [-1,1]

$$D' = \frac{D}{D_{max}}$$

where, if  $D > 0$ :

$$D_{max} = \min(p_A p_b, p_a p_B)$$

or if  $D < 0$ :

$$D_{max} = \max(-p_A p_B, -p_a p_b)$$

r correlation coefficient between the markers

$$r = \frac{-D}{\sqrt{(p_A * p_a * p_B * p_b)}}$$

where

- $p_A$  is defined as the observed probability of allele 'A' for marker 1,
- $p_a = 1 - p_A$  is defined as the observed probability of allele 'a' for marker 1,

- $p_B$  is defined as the observed probability of allele 'B' for marker 2, and
- $p_b = 1 - p_B$  is defined as the observed probability of allele 'b' for marker 2, and
- $p_{AB}$  is defined as the probability of the marker allele pair 'AB'.

For genotype data, AB/ab cannot be distinguished from aB/Ab. Consequently, we estimate  $p_{AB}$  using maximum likelihood and use this value in the computations.

### Value

LD returns an object of class LD, while LDband and LDdist return objects of classes LDband and LDdist, respectively. All classes contain these slots:

|          |                                                                     |
|----------|---------------------------------------------------------------------|
| call     | the matched call                                                    |
| D        | Linkage disequilibrium estimate                                     |
| Dprime   | Scaled linkage disequilibrium estimate                              |
| corr     | Correlation coefficient                                             |
| nobs     | Number of observations                                              |
| chisq    | Chi-square statistic for linkage equilibrium (i.e., $D=D'=corr=0$ ) |
| p.value  | Chi-square p-value for marker independence                          |
| LOD      | LOD scores                                                          |
| tab      | Description of 'tab'                                                |
| statlist | Description of 'statlist'                                           |
| which    | Description of 'which'                                              |
| object   | Description of 'object'                                             |

makeMarkerInfo      *makeMarkerInfo creates a dataframe of marker information*

---

**Description**

An auxilliary funtion to create a dataframe for the slot markerInfo of class geneSet

**Usage**

```
makeMarkerInfo(loci = character(0), transTable = loci)
```

**Arguments**

|            |                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------|
| loci       | a vector of makrer loci                                                                              |
| transTable | corresponding translation table for the markers at each locus.must have same length with vector loci |

**Value**

A dataframe with one row for each row in the callCodes slot of class geneSet. Include columns "Name" and "TransTable".

**Author(s)**

Scott Chasalow <Scott.Chasalow@bms.com>, Junsheng Cheng <cjsuicedu@yahoo.com>

---

makeTransTableList      *makeTransTableList creates a list of translation tables*

---

**Description**

Calls makeTransTable to create each item of the list.

**Usage**

```
makeTransTableList(alleleStringVec, listNames = NULL)
```

**Arguments**

|                 |                                          |
|-----------------|------------------------------------------|
| alleleStringVec | character vector such as c("12", "ACGT") |
| listNames       | names of translation tables              |

**Value**

If it is a LIST, use:

|       |                        |
|-------|------------------------|
| comp1 | Description of 'comp1' |
| comp2 | Description of 'comp2' |

...

**Examples**

```
## Not run:
## End(Not run) # End of \dontrun
```

---

makeTransTable      *makeTransTable creates a single translation table of the markers*

---

**Description**

Create a single translation table of the markers. It is called by makeTransTableList to make a list of translation tables.

**Usage**

```
makeTransTable(alleleString = "Aa", sep = "/", ploidy = 2)
```

**Arguments**

alleleString    character vector such as c("12", "ACGT")  
 sep            separation symbol of the alleles in alleleString  
 ploidy         Currently implemented only for ploidy=2

**Value**

a matrix of (# of alleles in alleleString)\textasciicircum2 by ploidy, and must include a column named "levels".

**Author(s)**

Scott Chasalow <Scott.Chasalow@bms.com>, Junsheng Cheng <cjsuicedu@yahoo.com>

---

markerInfo      *~~function to do ... ~~*

---

**Description**

~~ A concise (1-5 lines) description of what the function does. ~~

**Usage**

```
markerInfo(object, ...)  
markerInfo(object) <- value
```

**Arguments**

object        ~~Describe object here~~  
 value         ~~Describe value here~~  
 ...            ~~Describe ... here~~

**Details**

~~ If necessary, more details than the description above ~~

**Value**

markerSummary      *Generate allele, genotype, or LD summary objects*

---

### Description

Generate allele, genotype, or LD summary objects

### Usage

```
markerSummary(object,
              covariate = NULL,
              confidence = 0.95,
              alpha = 1 - confidence,
              show = TRUE,
              ...)
## S3 method for class 'markerSummary':
print(x, ...)
```

### Arguments

|            |                                                                                |
|------------|--------------------------------------------------------------------------------|
| object     | geneSet object                                                                 |
| covariate  |                                                                                |
| confidence | desired confidence interval for genotype and allele frequencies in each marker |
| alpha      | Type -1 error rate = (1- confidence)                                           |
| show       | No longer used                                                                 |
| x          | object of class 'markerSummary'                                                |
| ...        | optional additional arguments                                                  |

### Details

We can print the alleleSummary and genotypeSummary on screen, or save in html, tex, or pdf format using appropriate methods.

```

---

```
ped2geneSet          translate a ped matrix to a geneSet object
```

---

**Description**

Translate a ped matrix to a geneSet object.

**Usage**

```
ped2geneSet (pedObj, quiet=FALSE)
```

**Arguments**

`pedObj` a list with five elements: `ped`, `columns`, `markerNames`, `Position`, and `fileName`. `ped` is a pedigree data frame whose first 6 columns are family (pedigree id), pid (patient id), father (father id), mother (mother id), sex, affected (affection status). The remaining columns are pairs of marker alleles. Each row corresponds to an individual; `columns` are the names of the first 5 (or 6) columns of ped file. It should be either equal to `c("family", "pid", "father", "mother", "sex", "affected")` or equal to `c("family", "pid", "father", "mother", "sex")`; `founderOnly` indicates if using only founder info; `markerNames` is a vector of marker names; `Position` is a vector of marker positions; `fileName` is the pedigree file name.

`quiet` print intermediate results if `quiet=FALSE`.

**Value**

An object of `geneSet` class.

**Author(s)**

Weiliang Qiu <stwxq@channing.harvard.edu>, Ross Lazarus <ross.lazarus@channing.harvard.edu>

PerlegenExample      *Small example data set from Perlegen*

---

**Description**

Small example data set from Perlegen.

**Usage**

```
data(PerlegenExample)
```

**Format**

Object of class 'geneSet'.

**Details**

This data set is useful for testing, but the locus id's have been scrambled, and no covariate information is provided. As a consequence, the data is meaningless.

**Examples**

```
library(GeneticsBase)
data(PerlegenExample)
head(PerlegenExample)
```

---

PfizerExample      *Small example data set from Pfizer*

---

**Description**

Small example data set from Pfizer.

**Usage**

```
data(PfizerExample)
```

**Examples**

```
library(GeneticsBase)
data(PfizerExample)
head(PfizerExample)
```

---

PGtables                    *~~function to do ... ~~*

---

**Description**

~~ A concise (1-5 lines) description of what the function does. ~~

**Usage**

```
PGtables(x, filename = "", sep="_", format = c("print", "html", "latex"), ...)
```

**Arguments**

|          |                                                                                                                        |
|----------|------------------------------------------------------------------------------------------------------------------------|
| x        | ~~Describe x here~~                                                                                                    |

plot.LD

*Textual and graphical display of linkage disequilibrium (LD) objects***Description**

Textual and graphical display of linkage disequilibrium (LD) objects

**Usage**

```
plot(x, y, ...)
plot.LD(x, y=NULL, cex, ...)
LDView(LdMat,
        SNPloc=NULL,
        is.triangle=TRUE,
        SNPnames=NULL,
        cexSNPnames=0.2+1/log10(nrow(LdMat)),
        margins=c(6, 2, 3, 6),
        main=NULL,
        barCol=rainbow(256, start=0, end=1/6),
        widths=c(10, 10),
        heights=c(1, 10),
        ...)
```

**Arguments**

|             |                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | LD or LDband object                                                                                                                                             |
| y           | currently ignored                                                                                                                                               |
| cex         | Scaling factor for table text. If absent, text will be scaled to fit within the table cells.                                                                    |
| LdMat       | matrix of pair-wise LD measures                                                                                                                                 |
| SNPloc      | SNP locations                                                                                                                                                   |
| is.triangle | indicate if 'LdMat' is a lower triangle matrix or not. if 'LdMat' is an upper triangle, then the user has to transpose it before calling the function 'LDView'. |
| SNPnames    | labels for SNPs                                                                                                                                                 |
| cexSNPnames | font size for SNPs labels                                                                                                                                       |
| margins     | margins for heatmap                                                                                                                                             |
| main        | title for the plot                                                                                                                                              |

|         |                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------|
| barCol  | specify the color scheme                                                                                                 |
| widths  | The plot is split into two parts – upper part and lower part 'widths' specifies the widths of the two parts              |
| heights | The plot is split into two parts – upper part and lower part 'heights' specifies the heights of the two parts            |
| ...     | Optional arguments (plot.LD.data.frame passes these to LDtable and LDplot) and other parameters for the function 'image' |

### Details

LDtable generates a graphical matrix of LD coefficients. It attempts to properly set the font size so that the estimated values fit into the boxes. It also colorized the boxes to whether the estimates are significantly different from no linkage.

LDplot generates a plot of the LD coefficients across markers. By default it will overlay plots for LD against all markers. LD against a specific subset of markers can be obtained using the marker argument.

### Value

|          |                              |
|----------|------------------------------|
| SNPnames | labels of the SNPs in LDView |
| LdMat    | LD matrix                    |
| SNPloc   | SNP positions                |

 qtllex

*Simulated pedigree with genotypes and one qtl covariate*

---

**Description**

Simulated dataset for a pedigree of 1000 trios with 51 SNPs, and 1 quantitative trait.

**Usage**

```
data(qtllex)
```

**Format**

'geneSet' object

**Details**

This data is the 'qtl' example from Lange and Kraft's "Short Course: Genetics Association Analysis."

**Source**

Lange, C. and Kraft, P. (2005). "Short Course: Genetics Association Analysis."

**References**

Lange, C. and Kraft, P. (2005). "Short Course: Genetics Association Analysis."

DeMeo, D. L., C. Lange, et al. (2002). "Univariate and multivariate family-based association analysis of the IL-13 ARG130GLN polymorphism in the Childhood Asthma Management Program." *Genet Epidemiol* 23(4): 335-48.

**Examples**

```
library(GeneticsBase)
data(qtllex)
head(qtllex)
```

---

 readGenes.ped

*Function to read pedigree file format*

---

**Description**

Function to read pedigree file format

**Usage**

```
readGenes.ped(filename, columns = c("family", "pid", "father", "mother", "sex"),
              phase = list(FALSE), quiet = FALSE, missingval = c(0, ...))
readGenes.hapmap.ped(filename, ...)
readGenes.fbat.ped(filename, ...)
readGenes.pbat.ped(filename, ...)
```

**Arguments**

|            |                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename   | Name of the file in which data is stored                                                                                                                                                           |
| columns    | Name of the columns in the pedigree file - by default points to "family", "pid", "father", "mother", "sex"                                                                                         |
| phase      | 1. Yes/No for all (logical scalar) 2. Yes/No for each Marker (logical vector) 3. phaseObject (TBD): observation by marker by phase probabilities + definitions of contigs + probability of contigs |
| quiet      | Logical: whether the progress of reading the file should be displayed.                                                                                                                             |
| missingval | Missing values (if any) to obtain missingCodes                                                                                                                                                     |
| ...        | Additional arguments to function read.table                                                                                                                                                        |

**Author(s)**

---

readGenes.perlegen *Read Perlegen data files.*

---

**Description**

Read Perlegen data files.

**Usage**

```
readGenes.perlegen(filename, ..., quiet = FALSE)
```

**Arguments**

|          |                                                           |
|----------|-----------------------------------------------------------|
| filename | Name of the file in which data is stored                  |
| ...      | Additional arguments to scan                              |
| quiet    | Whether the progress of loading data should be displayed. |

**Author(s)**

Gregory R. Warnes <warnes@bst.rochester.edu> and Nitin Jain <nitin.jain@pfizer.com>

---

readGenes.pfizer *Read genetics data files that use Pfizer's data format.*

---

### Description

Read genetics data files that use Pfizer's data format.

### Usage

```
readGenes.pfizer(filename, phase=list(F),
                 format=c("Pivot", "Listing"),...)
```

### Arguments

|          |                                                            |
|----------|------------------------------------------------------------|
| filename | Name of the file in which data is stored                   |
| phase    | see below                                                  |
| format   | Format of the file to be read, one of "Pivot" or "Listing" |
| ...      | Additional arguments to function read.table                |

### Details

The argument `phase` may be:

- 1 A single logical scalar value that applies for all markers
- 2 A logical vector with one element per marker
- 3 A phaseObject (TBD) providing observation by marker by phase probabilities + definitions of contigs + probability of contigs

### Value

a geneSet object

### Author(s)

Gregory R. Warnes <warnes@bst.rochester.edu> and Nitin Jain <nitin.jain@pfizer.com>

### Examples

```
# store where we are now
here <- getwd()

# move to the data directory
dir <- file.path(.path.package("GeneticsBase"), "data")
setwd(dir)

# load Pfizer Data
PfizerExample <- readGenes.pfizer("PfizerExample.txt", format="Listing")

# look at the data
PfizerExample
```

```
# return to the original path
setwd(here)
```

---

|           |                                                       |
|-----------|-------------------------------------------------------|
| readGenes | <i>Import genetic data from standard file formats</i> |
|-----------|-------------------------------------------------------|

---

## Description

Import genetic data from standard file formats.

## Usage

```
readGenes(gfile, gformat=genotypeFileFormats, goptions=list(),
          pfile, pformat=phenotypeFileFormats, poptions=list(),
          mfile, mformat=markerFileFormats, moptions=list() )
```

## Arguments

|          |                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------|
| gfile    | File containing genotype data                                                                         |
| gformat  | Function, function name, or a character file format specification from the list genotypeFileFormats.  |
| goptions | Optional arguments for loading genotype data.                                                         |
| pfile    | File containing phenotype data                                                                        |
| pformat  | Function, function name, or a character file format specification from the list phenotypeFileFormats. |
| poptions | Optional arguments for loading phenotype data.                                                        |
| mfile    | File containing marker data                                                                           |
| mformat  | Function, function name, or a character file format specification from the list markerFileFormats.    |
| moptions | Optional arguments for loading marker data.                                                           |

## Details

Load genotype and (optionally) phenotype and marker information from the specified files and generate a geneSet object containing the results.

A variety of file formats are available. See the variables genotypeFileFormats, phenotypeFileFormats, phenotypeFileFormats for formats.

## Value

An object of class geneSet.

## Note

Adding a new genotype (phenotype) file format requires creation of a function named readGenes.newFormat (read.newFormat) and adding the string "newformat" to the vector genotypeFileFormats (phenotypeFileFormats).

Please submit new format functions to the authors for inclusion in the package.

**Description**

Read '.phe' phenotype file data

**Usage**

```
read.phe(filename, columns = c("family", "pid"), quiet = FALSE, ...)
read.fbat.phe(filename, columns = c("family", "pid"), quiet = FALSE, ...)
read.pbat.phe(filename, columns = c("family", "pid"), quiet = FALSE, ...)
```

**Arguments**

|          |                                                                                                                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filename | Name of the file                                                                                                                                                                                        |
| columns  | Column names for the first two columns of a pedigree file. Defaults to "family" and "pid", where "family" is a unique identifier for each family, and "pid" is a unique identifier for each individual. |
| quiet    | Logical indicating whether progress display is suppressed, Defaults to TRUE.                                                                                                                            |
| ...      | Additional (optional) parameters provided to function matrix                                                                                                                                            |

**Value**

A data frame containing the file

xbat

*Simulated pedigree with genotypes and covariates*

---

**Description**

Simulated dataset for a pedigree of 1000 trios with 50 SNPs, with 8 quantitative traits, 2 binary traits, and 8 covariates."

**Usage**

```
data(xbat)
```

**Format**

'geneSet' object

## Details

This data is the 'xbat' example from Lange and Kraft's "Short Course: Genetics Association Analysis." It is described there as:

"[This] simulated dataset comprises a pedigree file with genotype information for 1000 trios with 50 SNPs and a phenotype file that contains 8 quantitative traits, 2 binary traits, and 8 covariates.

"Genotypes

"The simulation generated complete genotype data for 1000 families with two parents and one offspring. The single nucleotide polymorphism (SNP) frequencies and haplotype blocks were estimated using real data. These estimates were fixed and used as parameters for the simulation of the parental genotypes. Offspring genotypes were generated by simulating random Mendelian transmission from their respective parents. In total, 50 SNPs were simulated, 28 of which lie in 1 of 5 variable length haplotype blocks (range: 4 to 10 SNPs per block). The blocks were simulated as a function of haplotype block frequency, assuming no recombination, resulting in varying degrees of linkage disequilibrium within each block. The remaining 22 SNPs that are not in a haplotype block were simulated randomly as a function of SNP frequency. The SNPs are indicated in the header line of the pedigree file, and named SNP1, SNP2, ..., and SNP50. Note that the affection status variable in the pedigree file is coded as missing (0) for all individuals. All phenotype data comes from the phenotype file (see below).

"Phenotypes

"Overall, 10 phenotypes ( $Y$ ) were simulated additively as function of the genetic effect size  $a$ , marker score  $X$ , covariate effect size  $b$ , and covariate value  $Z$  as follows:

$$Y_i = a_i X_i + b_i Z_i \quad (i = 1, 2, \dots, 10)$$

"Quantitative Traits

"Eight quantitative phenotypes were simulated from a random sample from a normal distribution:  $Y \sim N([aX + bZ], s^2)$ , where  $a$  is the additive effect for the phenotype and  $s^2$  is the variance. We measure the strength of the additive effect relative to the phenotypic variance by the heritability  $h^2$  [Falconer and Mackay, 1997], which is the proportion of phenotypic variation explained by genetic variation. We assume that the environment variance is 1. SNP23 was simulated as the "disease SNP" which is the 5th SNP in a 10 SNP haplotype block. The heritabilities were simulated from random uniform distribution ranging from -0.1 to 0.1. In addition, the simulation produced two correlated quantitative traits (QTL9 and QTL10;  $r^2 = 0.40$ ). The quantitative traits are indicated in the header line of the phenotype file and named QTL1, QTL2, ..., and QTL10.

"Binary Traits

"Two binary traits were simulated simply by dichotomizing the first quantitative trait (QTL1). For the AFF1 trait, individuals were coded as affected (1) if their QTL1 value is above the sample mean and unaffected (0) if their QTL1 value was below the sample mean. For the AFF2 trait, individuals were coded as affected (1) if their QTL1 value is at least one standard deviation above the sample mean, and missing ("-") if their trait value did not reach that criteria.

"Covariates

"In addition to the additive genetic effect, each phenotype was simulated with one covariate effect. The quantitative covariates were sampled from normal distribution ( $\mu = \text{random}$ ,  $s^2 = 10$ ). The effect size for each covariate was sampled randomly from a uniform distribution (0, 1). The covariates are indicated in the header line of the phenotype file and named COV1, COV2, ..., and COV10. Note that COV1 corresponds to QTL1, AFF1 and AFF2."

(quoted from Lange and Kraft 2005)
