BFSlevel

Build (generalized) hierarchy by Breath-First Search

## **Description**

BFSlevel builds a (generalized) hierarchy by Breath-First Search as described in (Yu and Gerstein, 2006)

#### Usage

```
BFSlevel(g,verbose=TRUE)
```

#### **Arguments**

g graphNEL object verbose Default: TRUE

#### **Details**

Haiyuan Yu and Mark Gerstein: Genomic analysis of the hierarchical structure of regulatory networks, PNAS 103(40):14724-14731, 2006

### Value

level vector of levels for each node

## Author(s)

Florian Markowetz <URL: http://genomics.princeton.edu/~florian>

## Examples

## bla

BoutrosRNAi2002

RNAi data on Drosophila innate immune response

### **Description**

Data from a study on innate immune response in *Drosophila* (Boutros et al, 2002). Selectively removing signaling components by RNAi blocked induction of all, or only parts, of the transcriptional response to LPS. The nested structure of perturbation effects allows to reconstruct a branching in the Imd pathway.

#### Usage

```
data(BoutrosRNAi2002)
```

#### **Format**

BoutrosRNAiExpression: data matrix: 14010 x 16 BoutrosRNAiDiscrete: binary matrix: 68 x 16

closest.transitive.greedy

#### 3

#### **Details**

The dataset consists of 16 Affymetrix-microarrays: 4 replicates of control experiments without LPS and without RNAi (negative controls), 4 replicates of expression profiling after stimulation with LPS but without RNAi (positive controls), and 2 replicates each of expression profiling after applying LPS and silencing one of the four candidate genes tak, key, rel, and mkk4/hep.

BoutrosRNAiExpression: For preprocessing we performed normalization on probe level using a variance stabilizing transformation (Huber et al, 2002), and probe set summarization using a median polish fit of an additive model (Irizarry et al, 2003).

BoutrosRNAiDiscrete: contains only the 68 genes more than two-fold up-regulated between negative and positive controls. The continuous expression values are discretized to 1 (effect: closer to negative controls) and 0 (no effect: closer to positive controls).

BoutrosRNAiDens: log p-value density matrix for the 68 genes with more than two-fold upregulated between negative and positive controls.

BoutrosRNAiLods: B-value matrix for the 68 genes with more than two-fold up-regulated between negative and positive controls.

BoutrosRNAiLogFC: matrix with log fold changes

```
closest.transitive.greedy
```

Find transitively closed graph most similar to the given one

#### **Description**

First, from the original graph  $\Phi$  spurious edges are pruned via prune.graph. Then the new graph  $\Phi'$  is transitively closed. Afterwards, the algorithms successively introduces new edges minimizing the distance to the original graph (defined as  $\sum_{ij} |\Phi_{ij} - \Phi'_{ij}|$ ) most. After each edge addition the graph is transitively closed again.

#### Usage

```
closest.transitive.greedy(Phi, verbose=TRUE)
```

4 enumerate.models

#### **Arguments**

Phi adjacency matrix

verbose do you want to see progress statements printed or not? Default: TRUE

#### Value

adjacency matrix

#### Author(s)

Holger Froehlich

#### See Also

```
prune.graph, \code{prune.graph}, \code{prune.graph}
```

enumerate.models

Exhaustive enumeration of models

#### **Description**

The function enumerate.models is used to create the model space for inference by exhaustive enumeration. It computes a list of all transitively closed directed graphs on a given number of nodes.

#### Usage

```
enumerate.models(x, name=NULL, trans.close=TRUE, verbose=TRUE)
```

#### **Arguments**

x either the number of nodes or a vector of node names. name optionally the nodenames, if they are not provided in x

trans.close should graphs be transitively closed?

verbose if TRUE outputs number of (unique) models. Default: TRUE

## **Details**

The model space of Nested Effects Models consists of all transitively closed directed graphs. The function enumerate.models creates them in three steps: (1.) build all directed graphs on x (or length (x)) nodes, (2.) transitively close each one of them, and (3.) remove redundant models to yield a unique set. So far, enumeration is limited to up to 5 nodes.

I'm aware that this is inefficient! It would be very desirable to enumerate the models directly (i.e. without creating all directed graphs as an intermediate step).

#### Value

a list of models. Each entry is a transitively closed adjacency matrix with unit main diagonal.

#### Author(s)

Florian Markowetz < URL: http://genomics.princeton.edu/~florian>

generateNetwork 5

#### See Also

nem

### **Examples**

```
enumerate.models(2)
enumerate.models(c("Anna", "Bert"))
```

generateNetwork

Random networks and data sampling

#### **Description**

1. Random network generation; 2. sampling of data from a given network topology

#### Usage

```
sampleRndNetwork(Sgenes, scaleFree=TRUE, gamma=2.5, maxOutDegree=length(Sgenes),
sampleData(Phi, m, prob=NULL, uninformative=0, type="binary", replicates=4, type
```

#### **Arguments**

Sgenes character vector of S-genes

scaleFree should the network topology be scale free?

gamma for scale free networks: out-degrees of nodes are sampled from  $\frac{1}{Z}*(0:maxOutDegree)^{-\gamma}$ ,

where Z is a normalization factor

maxOutDegree maximal out-degree of nodes

maxInDegree maximal in-degree of nodes prior to transitive closure

trans.close Should the transitive closure of the graph be returned? Default: TRUE

DAG Should only DAGs be sampled? Default: FALSE

Phi adjacency matrix

m number of E-genes to sample

prob probability for each S-gene to get an E-gene attached

uninformative

additional number of uninformative E-genes, i.e. E-genes carrying no informa-

tion about the nested structure

type "binary" = binary data; "density" = log 'p-value' densities sampled from beta-

uniform mixture model; "lodds" = log odds sampled from two normal distribu-

tions

replicates number of replicate measurements to simulate for binary data

typeI.err simulated type I error for binary data
typeII.err simulated type II error for binary data

alpha parameter for  $Beta(\alpha,1)$  distribution: one parameter per S-gene beta parameter for  $Beta(1,\beta)$  distribution: one parameter per S-gene

6 generateNetwork

lambda	mixing coefficients for beta-uniform mixture model of the form: $\lambda_1 + \lambda_2 * Beta(\alpha,1) + \lambda_3 * Beta(1,\beta)$ . There is a vector of 3 mixing coefficients per model and one model per S-gene.
meansH1	normal distribution means of log odds ratios under the hypothesis of expecting an effect: one mean per S-gene
meansH0	normal distribution means of log odds ratios under the null hypothesis: one mean per S-gene
sdsH1	normal distribution standard deviations of log odds values under the hypothesis of expecting an effect: one sd per S-gene
sdsH0	normal distribution standard deviations of log odds values under the null hypothesis: one sd per S-gene

### **Details**

Random networks are generated as follows: For each S-gene  $S_k$  we randomly choose the number o of outgoing edges between 0 and maxOutDegree. This is either done uniform randomly or, if scale free networks are created, according to a power law distribution specified by gamma. We then select o S-genes having at most maxInDegree ingoing edge and connected  $S_k$  to them.

The function sampleData samples data from a given network topology as follows: We first attach E-genes to S-genes according to the probabilities prob (default: uniform). We then simulate knockdowns of the individual S-genes. For those E-genes, where no effects are expected, values are sampled from a null distribution, otherwise from an alternative distribution. In the simplest case we only sample binary data, where 1 indicates an effect an 0 no effect. Alternatively, we can sample log "p-value" densities according to a beta-uniform mixture model, where the null distribution is uniform and the alternative a mixture of two beta distributions. A third possibility is to sample log odds ratios, where alternative and null distribution are both normal.

#### Value

For sampleRndNetwork an adjacency matrix, for sampleData a data matrix, for sampleData.BN a data matrix and a linking of effects to signals.

#### Author(s)

Holger Froehlich http://www.dkfz.de/mga2/people/froehlich, Cordula Zeller

#### See Also

```
getDensityMatrix
```

## Examples

```
Phi = sampleRndNetwork(paste("S",1:5,sep=""))
D = sampleData(Phi, 100, type="density")$D
plot(as(transitive.reduction(Phi), "graphNEL"), main="original graph")
x11()
plot.nem(nem(D, control=set.default.parameters(unique(colnames(D)), type="CONTmLI")
```

getDensityMatrix 7

getDensityMatrix Calculate density matrix from raw p-value matrix

### **Description**

Fit a 3 component BUM model to each column of a raw p-value matrix.

## Usage

getDensityMatrix(Porig, dirname=NULL, startab=c(0.3,10), startlam=c(0.6,

### **Arguments**

Porig	matrix of raw p-values
dirname	name of a directory to save histograms and QQ-plots to. If dirname=NULL, then the plots are made to the screen, and after each fit the user is asked to press a key in order to continue.
startab	start values for alpha and beta parameter
startlam	start values for mixing coefficients
tol	convergence tolerance: If the absolute likelihood ratio -1 becomes smaller than this value, then the EM algorithm is supposed to be converged.

## **Details**

The BUM density model consists of 3 components:  $f(x) = lambda\_1 + lambda\_2 * dbeta(x, alpha, 1) + lambda\_3 * dbeta(x, 1, beta)$ . The mixing coefficients and the parameters alpha and beta are fitted together via an EM algorithm.

## Value

log-density matrix of same dimensions as Porig: The log-densities can be interpreted as log signal-to-noise ratios. A value > 0 means higher signal than noise, and a value < 0 a higher noise than signal.

## Note

Note the difference to the previous package version: the LOG-density is returned now!

## Author(s)

Holger Froehlich

8 infer.edge.type

infer.edge.type

Infer regulation direction for each edge

#### **Description**

The method infers edge types (up-regulation, down-regulation) for a given nem model. For an edge a->b the method looks at the fraction of E-genes attached to b (including b itself), which are up-or down-regulated in a knock-down of a. If significantly more genes are down-regulated than up-regulated, the edge a->b is assumed to be an activation. Likewise, if significantly more genes are up-regulated than down-regulated, a->b is assumed to be an inhibition. If there is no significant difference in up- and down-regulated edges, a->b does not have a specified type.

## Usage

```
infer.edge.type(x, logFC, alpha=0.05, adj.method="BY")
```

#### **Arguments**

x nem object

logFC matrix with fold changes. The rownames of this matrix should correspond to the

rownames of the data matrix, which was used to infer the nem model.

alpha p-value cutoff

adj.method multiple testing correction method. Default: Benjamini-Yekutieli

#### **Details**

Significance is calculated using a two-tailed binomial test with null hypothesis p=0.5.

#### Value

Modified nem object. Each edge in the nem graph now has a "weight" and a "label" attribute. The label attribute corresponds to the original value in the adjacency matrix. The weight attribute encodes up- and down-regulation in the following way: value 2 means up-regulation, value -1 down-regulation and value 1 corresponds to an unknown regulation type.

#### Author(s)

Holger Froehlich

binom.test

#### **Examples**

```
data("BoutrosRNAi2002")
D <- BoutrosRNAiDiscrete[,9:16]
result = nem(D, control=set.default.parameters(unique(colnames(D)), para=c(0.13,0)
resEdgeInf = infer.edge.type(result, BoutrosRNAiLogFC)
plot.nem(resEdgeInf)</pre>
```

internal 9

internal internal functions

### **Description**

internal functions: do not call these functions directly.

## Usage

various

## **Arguments**

various

#### Value

various

## Author(s)

Holger Froehlich

local.model.prior Computes a prior to be used for edge-wise model inference

## Description

The function pairwise.posterior infers a phenotypic hierarchy edge by edge by choosing between four models (unconnected, subset, superset, undistinguishable). For each edge, local.model.prior computes a prior distribution over the four models. It can be used to ensure sparsity of the graph and high confidence in results.

### Usage

```
local.model.prior(size,n,bias)
```

## **Arguments**

size expected number of edges in the graph.

n number of perturbed genes in the dataset, number of nodes in the graph

bias the factor by which the double-headed edge is preferred over the single-headed

edges

10 nem.bootstrap

#### **Details**

A graph on n nodes has N=n\*(n-1)/2 possible directed edges (one- or bi-directional). If each edge occurs with probability p, we expect to see Np edges in the graph. The function local.model.prior takes the number of genes (n) and the expected number of edges (size) as an input and computes a prior distribution for edge occurrence: no edge with probability size/N, and the probability for edge existence being split over the three edge models with a bias towards the conservative double-headed model specified by bias. To ensure sparsity, the size should be chosen small compared to the number of possible edges.

#### Value

a distribution over four states: a vector of four positive real numbers summing to one

## Author(s)

Florian Markowetz <URL: http://genomics.princeton.edu/~florian>

#### See Also

```
pairwise.posterior, nem
```

#### **Examples**

    nem.bootstrap(D, control=set.default.parameters(unique(colnames(D)), para=c(0.13,0.05))
## End(Not run)</pre>
```

```
nem.calcSignificance
```

Statistical significance of network hypotheses

## Description

Assess statistical significance of a network hypothesis by comparing it to a null hypothesis.

## Usage

```
nem.calcSignificance(D, x, N=1000, seed=1)
```

## Arguments

seed

D data matrix with	•
x nem object	
N number of rando	m networks to sample

random seed

12 nem.consensus

#### **Details**

Given data, N random network hypotheses from a null distribution are drawn as follows: For each S-gene  $S_k$  we randomly choose a number o of outgoing edges between 0 and 3. We then select o S-genes having at most 1 ingoing edge, connected  $S_k$  to them and transitively closed the graph. For all random network hypotheses it is counted, how often their likelihood is bigger than that of the given network. This yields an exact p-value.

Another way of assessing the statistical significance of the network hypothesis is to draw random permutations of the node labels. Note that in this case the node degree distribution is the same as in the given network. Again, we can obtain an exact p-value by counting, how often the likelihood of the permuted network is bigger than that of the given network.

Finally, comparison to randomly perturbed networks (insertion or deletion of 1 edge) yields an exact p-value describing the stability of the network.

#### Value

#### Author(s)

Holger Froehlich

## See Also

```
nem.consensus, nem.jackknife, nem.bootstrap, nem
```

## **Examples**

nem.consensus

Statistically stabile nested effects models

#### **Description**

Performs bootstrapping (resampling with replacement) on E-genes and jackknife on S-genes to assess the statistical stability of networks. Only edges appearing with a higher frequency than a predescribed threshold in both procedures are regarded as statistical stable and appear in the so-called consensus network.

nem.consensus 13

#### Usage

```
nem.consensus(D,thresh=0.5, nboot=1000,inference="nem.greedy",models=NULL,contro
## S3 method for class 'nem.consensus':
print(x, ...)
```

### **Arguments**

D	data matrix with experiments in the columns (binary or continous)
thresh	only edges appearing with a higher frequency than "thresh" in both, bootstrap and jackknife procedure, are regarded as statistically stable and trust worthy
nboot	number of bootstrap samples desired
inference	search to use exhaustive enumeration, triples for triple-based inference, pairwise for the pairwise heuristic, ModuleNetwork for the module based inference, nem.greedy for greedy hillclimbing, nem.greedyMAP for alternating MAP optimization using log odds or log p-value densities
models	a list of adjacency matrices for model search. If NULL, an exhaustive enumeration of all possible models is performed.
control	list of parameters: see set.default.parameters
verbose	do you want to see progression statements? Default: TRUE
Х	nem object

#### **Details**

Calls nem or nemModelSelection internally, depending on whether or not lambda is a vector and Pm != NULL.

## Value

```
consensus network (nem object)
```

## Author(s)

Holger Froehlich

#### See Also

```

```

other arguments to pass

### **Examples**

```
## Not run:
    data("BoutrosRNAi2002")
    D <- BoutrosRNAiDiscrete[,9:16]
    nem.consensus(D, control=set.default.parameters(unique(colnames(D)), para=c(0.13,0.05))
## End(Not run)</pre>
```

14 nem.cont.preprocess

```
nem.cont.preprocess
```

Calculate classification probabilities of perturbation data according to control experiments

### **Description**

Calculates probabilities of data to define effects of interventions with respect to wildtype/control measurements

## Usage

```
nem.cont.preprocess(D,neg.control=NULL,pos.control=NULL,nfold=2, influencefactor
```

### **Arguments**

D	matrix with experiments as columns and effect reporters as rows	
neg.control	either indices of columns in $\ensuremath{D}$ or a matrix with the same number of rows as $\ensuremath{D}$	
pos.control	either indices of columns in ${\mathbb D}$ or a matrix with the same number of rows as ${\mathbb D}$	
nfold	fold-change between neg. and pos. controls for selecting effect reporters. Default: $\boldsymbol{2}$	
influencefactor		
	factor multiplied onto the probabilities, so that all negative control genes are treated as influenced, usually automatically determined	
empPval	empirical p-value cutoff for effects if only one control is available	
verbose	Default: TRUE	

## Details

Determines the empirical distributions of the controls and calculates the probabilities of pertubartion data to belong to the control distribution(s).

## Value

dat	data matrix	
pos	positive controls [in the two-controls setting]	
neg	negative controls [in the two-controls setting]	
sel	effect reporters selected [in the two-controls setting]	
prob.influenced		
	probability of a reporter to be influenced	
influencefac	tor	
	factor multiplied onto the probabilities, so that all negative control genes are treated as influenced	

#### Note

preliminary! will be developed to be more generally applicable

nem.discretize 15

#### Author(s)

## **Examples**

```
data("BoutrosRNAi2002")
preprocessed <- nem.cont.preprocess(BoutrosRNAiExpression, neg.control=1:4, pos.control=</pre>
```

nem.discretize

Discretize perturbation data according to control experiments

## Description

discretizes raw data to define effects of interventions with respect to wildtype/control measurements

### Usage

```
nem.discretize(D,neg.control=NULL,pos.control=NULL,nfold=2,cutoff=0:10/10, pCour
```

## Arguments

D	matrix with experiments as columns and effect reporters as rows
neg.control	either indices of columns in $\ensuremath{D}$ or a matrix with the same number of rows as $\ensuremath{D}$
pos.control	either indices of columns in $\ensuremath{\mathbb{D}}$ or a matrix with the same number of rows as $\ensuremath{\mathbb{D}}$
nfold	fold-change between neg. and pos. controls for selecting effect reporters. Default: $\boldsymbol{2}$
cutoff	a (vector of) cutoff value(s) weighting the pos. controls versus the neg. controls. Default: $0.10/10$
pCounts	pseudo-counts to guard against unreasonable low error estimates
empPval	empirical p-value cutoff for effects if only one control is available
verbose	Default: TRUE

#### **Details**

Chooses cutoff such that separation between negative and positive controls becomes optimal.

16 nem.jackknife

#### Value

dat	discretized data matrix
pos	discretized positive controls [in the two-controls setting]
neg	discretized negative controls [in the two-controls setting]
sel	effect reporters selected [in the two-controls setting]
cutoff	error rates for different cutoff values [in the two-controls setting]
para	estimated error rates [in the two-controls setting]

#### Note

preliminary! will be developed to be more generally applicable

```

nem

Nested Effects Models - main function

### **Description**

The main function to perform model learning from data

19 nem

#### **Usage**

```
nem(D,inference="nem.greedy",models=NULL,control=set.default.parameters(setdiff())
## S3 method for class 'nem':
print(x, ...)
```

### Arguments

D	data matrix with experiments in the columns (binary or continious)
inference	search to use exhaustive enumeration, triples for triple-based inference, pairwise for the pairwise heuristic, <code>ModuleNetwork</code> for the module based inference, <code>nem.greedy</code> for greedy hillclimbing, <code>nem.greedyMAP</code> for alternating MAP optimization using log odds or log p-value densities
models	a list of adjacency matrices for model search. If NULL, an exhaustive enumeration of all possible models is performed.
control	list of parameters: see set.default.parameters
verbose	do you want to see progression statements? Default: TRUE
X	nem object

#### **Details**

If parameter Pm!= NULL and parameter lambda == 0, a Bayesian approach to include prior knowledge is used. Alternatively, the regularization parameter lambda can be tuned in a model selection step via the function nemModelSelection using the BIC criterion. If automated subset selection of effect reporters is used and parameter type == CONTmLLMAP, the regularization parameter delta is tuned via the AIC model selection criterion. Otherwise, an iterative algorithm is executed, which in an alternating optimization scheme reconstructs a network given the current set of effect reporters and then selects the effect reporters having the highest likelihood under the given network. The procedure is run until convergence.

The function plot . nem plots the inferred phenotypic hierarchy as a directed graph, the likelihood distribution of the models (only for exhaustive search) or the posterior position of the effected genes.

## Value

graph	the inferred directed graph (graphNEL object)
mLL	log posterior marginal likelihood of final model

network.AIC

AIC/BIC criterion for network graph

## Description

Calclate AIC/BIC for a given network graph (should be transitively closed). The number of free parameters equals the number of unknown edges in the network graph.

## Usage

```
network.AIC(network, Pm=NULL, k=length(nodes(network$graph)), verbose=TRUE)
```

## Arguments

```
network a nem object (e.g. 'pairwise')

Pm prior over models (n x n matrix). If NULL, then a matrix of 0s is assumed k penalty per parameter in the AIC/BIC calculation. k = 2 for classical AIC verbose print out the result
```

## **Details**

For k = log(n) the BIC (Schwarz criterion) is computed. Usually this function is not called directly but from nemModelSelection

#### Value

plotEffects

Plots data according to a phenotypic hierarchy

### **Description**

plotEffects visualizes the subset structure in the data by reordering rows and columns according to the topological order given by a phenotypic hierarchy.

#### Usage

```
plotEffects(D, nem, border=TRUE, legend=TRUE, order=NULL, orderSCC=TRUE, palette="Blue
```

### **Arguments**

D	data matrix
nem	phenotypic hierarchy (object of class 'score' or 'pairwise')
border	draw red lines to indicate gene-specific effect reporters. Default: TRUE
legend	plot a legend. Default: TRUE
order	pre-define an order of the S-genes instead of the topological order to visualize the subset structure. Default: Use topological order.
orderSCC	Is the pre-defined order given on strongly connected components rather than on individual nodes?
palette	color palette to use: either 'BlueRed' (default) or 'Grey'
	additional parameters for the graphics function 'image'

#### **Details**

The experiments in the columns are reordered according to the topological order given by a phenotypic hierarchy. The effect reporters in the rows are grouped together by their position in the hierarchy. The groups are then arranged by topological order. Within each group the rows are hierarchically clustered.

22 plot.nem

#### Value

ordering of the E-genes according to the hierarchy (vector of indices)

#### Note

This function was formerly named plot.effects. This naming is not possible any more, since S3 classes were used for the function plot.nem.

#### Author(s)

 $Florian\ Markowetz\ < URL:\ http://genomics.princeton.edu/\sim florian\ >,\ Holger\ Froehlich\ < URL:\ http://www.dkfz.de/mga2/princeton.edu/\sim florian\ >,\ Holger\ Froehlich\ >,\ Holger\ Froehlic$ 

#### **Examples**

```
data("BoutrosRNAi2002")
D <- BoutrosRNAiDiscrete[,9:16]
res <- nem(D,control=set.default.parameters(unique(colnames(D)), para=c(.13,.05)))
plotEffects(D,res)</pre>
```

plot.nem

plot nested effect model

#### **Description**

plot graph of nested effects model, the marginal likelihood distribution or the posterior position of the effected genes

## Usage

```
## S3 method for class 'nem':
plot(x, what="graph", remove.singletons=FALSE, PDF=FALSE, filename="nemp
```

#### **Arguments**

SCC

```
nem object to plot
Х
                  (i), "graph", (ii) "mLL" = likelihood distribution, (iii) "pos" = posterior position
what
                  of effected genes
remove.singletons
                  remove unconnected nodes from the graph plot
PDF
                  output as PDF-file
                  filename of PDF-file
filename
                  if x has a real valued adjacency matrix (weight matrix), don't plot edges with
thresh
                  |weight| <= thresh
transitiveReduction
                  plot a transitively reduced graph
                  plot edge weights/probabilities. If regulation directions have been inferred (see
plot.probs
                  infer.edge.type), upregulated edges are drawn red and downregulated
                  edges blue. Edges, were no clear direction could be inferred, are drawn in black.
```

plot the strongly connected components graph

prune.graph 23

D Visualize the nested subset structure of the dataset via plotEffects along with the graph and show the linking of E-genes to S-genes in the dataset. Should only be used for small networks. Default: Just plot the graph draw.lines If the nested subset structure is shown, should additionally lines connecting Sgenes and their associated E-genes be drawn? WARNING: For larger datasets than e.g. 5 S-genes this most probably does not work, because the nested subset structure picture then partially overlaps with the graph picture. Default: Do not

color palette to use: either 'BlueRed' (default) or 'Grey' palette

other arguments to be passed to the Rgraphviz plot function or to the graphics

'image' function.

#### Value

none

#### Author(s)

Florian Markowetz < URL: http://genomics.princeton.edu/~florian>, Holger Froehlich < URL: http://www.dkfz.de/mga2/

#### See Also

```
nem, plotEffects, infer.edge.type
```

prune.graph Prunes spurious edges in a phenotypic hierarchy	prune.graph	Prunes spurious edges in a phenotypic hierarchy	
---	-------------	---	--

#### **Description**

A heuristic to prune spurious edges in a pehnotypic hierarchy

#### Usage

```
prune.graph(g,cutIN=NULL,cutOUT=NULL,quant=.95,verbose=TRUE)
```

## **Arguments**

g	an adjacency matrix or a 'graphNEL' object
cutIN	minimum number of missing in-edges required to cut all in-edges. Default
cutOUT	minimum number of missing out-edges required to cut all out-edges
quant	if 'cutIN' or 'cutOUT' are not assigned, a quantile 'quant' of the distribution of missing in- or out-edges for all nodes is used
verbose	Default: TRUE

#### **Details**

prune.graph provides a heuristic approach to prune surious edges. prune.graph compares the input graph to its transitive closure, and counts for each node how many incoming and outgoing edges are missing. If the number is bigger than a user-defined cutoff, all incoming (outgoing) edges are removed.

24 SahinRNAi2008

#### Value

```
graph the pruned phenotypic hierarchy (a 'graphNEL' object)
removed number of removed edges
missing.in number of missing in-edges for each node
missing.out number of missing out-edges for each node
```

#### Author(s)

Florian Markowetz <URL: http://genomics.princeton.edu/~florian>

## **Examples**

```
# a transitively closed core with two spurious edges
g <- matrix(0,5,5)
g[1,2] <- 1
g[2,c(3,4)] <- 1
g[3,4] <- 1
g[4,5] <- 1
dimnames(g) <- list(LETTERS[1:5], LETTERS[1:5])
g <- as(g, "graphNEL")

# prune graph
gP <- prune.graph(g)

par(mfrow=c(1,2))
plot(g,main="two spurious edges")
plot(gP$graph,main="pruned")</pre>
```

SahinRNAi2008

Combinatorial Protein Knockdowns in the ERBB Signaling Pathway

## Description

Sixteen RNAi knockdowns (including 3 double knockdowns) of proteins in the ERBB signaling pathway of trastuzumab resistant breast cancer cells were conducted. Reverse Phase Protein Array (RPPA) measurments for 10 signaling intermediates are available before and after EGF stimulation with 4 technical and 3 biological replicates.

#### Usage

```
data(SahinRNAi2008)
```

#### **Format**

dat.unnormalized: 408 x 17 matrix (rows = RPPA measurements for (16 KOs + MOCK) x 4 technical x 3 biological replicates, columns = 10 antibodies + 6 proteins without measurements + time) dat.normalized: 408 x 17 matrix (measurements from technical and biological replicates are quantile normalized for each RNAi experiment)

SCCgraph 25

#### **Details**

The cells were lysed on ice by scraping the cells in M-PER lysis buffer (Pierce, Rockford, IL) containing protease inhibitor Complete Mini (Roche, Basel), anti-phosphatase PhosSTOP (Roche, Basel), 10 mM NaF and 1mM Na4VO3. Protein concentrations were determined with a BCA Protein Assay Reagent Kit (Pierce, Rockford, IL). Lysates were mixed 1:2 with 2 times Protein Arraying Buffer (Whatman, Brentfort, UK) to obtain a final protein concentration of 1.5 mug/muL. Briefly, these lysates were printed onto nitrocellulose coated ONCYTE-slides (Grace Bio Labs, Bend, USA) using a non-contact piezo spotter, sciFlexxarrayer S5 (Scienion, Berlin, Germany). After primary and near-infrared (NIR)-dye labeled secondary antibodies applied, spots were analysed using an Odyssey scanner (LI-COR, Lincoln, USA) and signal intensities were quantified using Odyssey 2.0 software (For detailed information and an antibody list, see Sahin et al., 2008). Since no antibody against MEK1 was available, we measured protein expression of pERK1/2, which is downstream of MEK1.

SCCgraph

Combines Strongly Connected Components into single nodes

## Description

SCCgraph is used to identify all nodes which are not distinguishable given the data.

## Usage

```
SCCgraph (x, name=TRUE, nlength=20)
```

#### **Arguments**

x graphNEL object or an adjacency matrix

name Concatenate all names of summarized nodes, if TRUE, or number nodes, if

FALSE. Default: TRUE

nlength maximum length of names

26 getRelevantEGenes

#### **Details**

A graph inferred by either nem or nemModelSelection may have cycles if some phenotypic profiles are not distinguishable. The function SCCgraph identifies cycles in the graph (the strongly conneced components) and summarizes them in a single node. The resulting graph is then acyclic.

### Value

```
a graphNEL object with connected components of the input graph summarized into single nodes

scc a list mapping SCCs to nodes

which.scc a vector mapping nodes to SCCs
```

### Author(s)

Florian Markowetz < URL: http://genomics.princeton.edu/~florian>, Holger Froehlich < URL: http://www.dkfz.de/mga2/j

res <- nem(D,control=set.default.parameters(unique(colnames(D)), para=c(.13,.05)))
#
sccg <- SCCgraph(res$graph,name=TRUE)
#
par(mfrow=c(1,2))
plot.nem(res, main="inferred from data")
plot(sccg$graph, main="condensed (rel,key)")</pre>
```

getRelevantEGenes Automatic selection of most relevant effect reporters

## Description

1. A-priori filtering of effect reporters/E-genes: Select effect reporters, which show a pattern of differential expression across experiments that is expected to be non-random. 2. Automated effect reporters subset selection: Select those effect reporters, which have the highest likelihood under the given network hypothesis.

#### Usage

```
filterEGenes(Porig, D, Padj=NULL, ntop=100, fpr=0.05, adjmethod="bonferroni", cu getRelevantEGenes(Phi, D, control, nEgenes=min(10*nrow(Phi), nrow(D)))
```

getRelevantEGenes 27

#### **Arguments**

#### For method filterEGenes:

Porig matrix of raw p-values, typically from the complete array

D data matrix. Columns correspond to the nodes in the silencing scheme. Rows

are effect reporters.

Pad j matrix of false positive rates. If not, provided Benjamini-Hochbergs method for

false positive rate computation is used.

ntop number of top genes to consider from each knock-down experiment

fpr significance cutoff for the FDR

adjmethod adjustment method for pattern p-values

cutoff significance cutoff for patterns

Phi adjacency matrix with unit main diagonal

control list of parameters: see set.default.parameters

nEgenes no. of E-genes to select

#### **Details**

The method filterEGenes performs an a-priori filtering of the complete microarray. It determines how often E-genes are expected to be differentially expressed across experiments just randomly. According to this only E-genes are chosen, which show a pattern of differential expression more often than can be expected by chance.

The method getRelevantEGenes looks for the E-genes, which have the highest likelihood under the given network hypothesis. In case of the scoring type "CONTmLLBayes" these are all E-genes which have a positive contribution to the total log-likelihood. In case of type "CONTmLLMAP" all E-genes not assigned to the "null" S-gene are returned. This involves the prior probability delta/no. S-genes for leaving out an E-gene. For all other cases ("CONTmLL", "FULLmLL", "mLL") the nEgenes E-genes with the highest likelihood under the given network hypothesis are returned.

#### Value

I index of selected E-genes

dat subset of original data according to I

patterns significant patterns

nobserved no. of cases per observed pattern

selected selected E-genes

mLL marginal likelihood of a phenotypic hierarchy

pos posterior distribution of effect positions in the hierarchy

mappos Maximum a posteriori estimate of effect positions

LLperGene likelihood per selected E-gene

#### Author(s)

Holger Froehlich

28 set.default.parameters

#### **Examples**

```
# Drosophila RNAi and Microarray Data from Boutros et al, 2002
data("BoutrosRNAi2002")
D <- BoutrosRNAiDiscrete[,9:16]

# enumerate all possible models for 4 genes
Sgenes = unique(colnames(D))
models <- enumerate.models(Sgenes)

getRelevantEGenes(models[[64]], D, control=set.default.parameters(Sgenes, para=c(.13,...))</pre>
```

```
set.default.parameters
```

Get/set hyperparameters

#### **Description**

Allows to set and retrieve various hyperparameters for different inference methods.

#### Usage

```
set.default.parameters(Sgenes, ...)
```

#### **Arguments**

```
Sgenes character vector of S-gene identifiers
... parameters to set (see details)
```

#### **Details**

Since version 2.5.4 functions in the nem package do not have any more a large amount of individual parameters. Instead there is just one hyperparameter, which is passed to all functions. Parameter values with the hyperparameter can be set with this function.

type mLL or FULLmLL or CONTmLL or CONTmLLBayes or CONTmLLMAP or gnem. CONTmLLDens and CONTmLLRatio are identical to CONTmLLBayes and CONTmLLMAP and are still supported for compatibility reasons. mLL and FULLmLL are used for binary data (see BoutrosRNAiDiscrete) and CONTmLL for a matrix of effect probabilities. CONTmLLBayes and CONTmLLMAP are used, if log-odds ratios, p-value densities or any other model specifies effect likelihoods. CONTmLLBayes refers to an inference scheme, were the linking positions of effect reporters to network nodes are integrated out, and CONTmLLMAP to an inference scheme, were a MAP estimate for the linking positions is calculated. gnem indicates Generalized Nested Effects Models (GNEMs).

para vector of length two: false positive rate and false negative rate for binary data. Used by mLL

hyperpara vector of length four: used by FULLmLL() for binary data

**Pe** prior of effect reporter positions in the phenotypic hierarchy (same dimension as D). Not used type gnem. Default: NULL

Pm prior over models (n x n matrix). Default: NULL

set.default.parameters 29

**Pmlocal** local model prior for pairwise and triple learning. For pairwise learning generated by local.model.prioraccording to arguments local.prior.size and local.prior.bias

- **local.prior.size** prior expected number of edges in the graph (for pairwise learning). Default: no. nodes
- local.prior.bias bias towards double-headed edges. Default: 1 (no bias; for pairwise learning)
- triples.thrsh threshold for model averaging to combine triple models for each edge. Default: 0.5
- **lambda** regularization parameter to incorporate prior assumptions. May also be a vector of possible values, if nemModelSelection is used, Default: 0 (no regularization)
- **delta** regularization parameter for automated subset selection of effect reporters (CONTmLLMAP only). Default: 1/no. nodes
- **selEGenes** automated E-gene subset selection (includes tuning of delta for CONTmLLMAP). Default: FALSE
- **trans.close** Should always transitive closed graphs be computed? Default: TRUE. NOTE: This has only an impact for type nem.greedyMAP and gnem. Default: TRUE
- **backward.elimination** For module networks and greedy hillclimbing inference: Try to eliminate edges increasing the likelihood. Works only, if trans.close=FALSE. Default: FALSE
- mode For Bayesian network inference and GNEMs: binary\_ML: effects come from a binomial distribution ML learning of parameters (Bayesian networks only); binary\_Bayesian: effects come from a binomial distribution Bayesian learning of parameters (Bayesian networks only); continous\_ML: effects come from a normal distribution ML learning of parameters; continous\_Bayesian: effects come from a normal distribution Bayesian learning of parameters.
- **nu.intervention, lambda.intervention** For gnem: For any perturbed node we suppose the unknown mean mu given its unknown variance sigma2 to be drawn from N(nu.intervention, sigma2/lambda.intervention). Default: nu.intervention=0.6, lambda.intervention=4
- **nu.no\_intervention, lambda.no\_intervention** The same parameters for unperturbed nodes. Default: nu.no\_intervention=0.95, lambda.no\_intervention=4
- **df.intervention, scale.intervention** For gnem: The unknown variance sigma 2 for perturbed nodes is supposed to be drawn from Inv- $\chi^2$ (df.intervention, scale.intervention). Default: df.intervention=4.4, scale.intervention=4.4
- **df.no\_intervention, scale.no\_intervention** The same parameters for unperturbed nodes. Default: df.no\_intervention=4.4, scale.no\_intervention=0.023
- **map** For gnem: Mapping of interventions to network nodes. The format is a named list of strings with names being the interventions and entries being the network nodes. Default: Entries and names are the network nodes.
- **outputdir** Directory where to put diagnostic plots. Default: folder "QualityControl" in current working directory
- debug Print out or plot diagnostic information. Default: FALSE

#### Value

A list containing all parameters described above.

## Author(s)

Holger Froehlich < URL: http://www.dkfz.de/mga2/people/froehlich>

#### **Examples**

```
control = set.default.parameters(LETTERS[1:5], type="CONTmLLBayes", selEGenes=TRUE) # set
```

30 subsets

sim.intervention Simulate interventions in a Nested Effects Model

## Description

Simulates a knock-down of a list of network nodes and returns the network nodes and effect reporters, where effects are expected.

## Usage

```
sim.intervention(x, int)
```

### **Arguments**

x nem object

int a character vector of nodes in the network

#### Value

list with two slots:

Sgenes.effected

effected network nodes

Egenes.effected

effected downstream effect reporters

### Author(s)

Holger Froehlich

### **Examples**

```
data("BoutrosRNAi2002")
D <- BoutrosRNAiDiscrete[,9:16]
res = nem(D, control=set.default.parameters(unique(colnames(D)), para=c(0.13,0.05)))
sim.intervention(res, "rel") # simulate knock-down of rel</pre>

## **Examples**

## bla

transitive.closure Computes the transitive closure of a directed graph

## Description

Computes the transitive closure of a graph. Introduces a direct edge whenever there is a path between two nodes in a digraph.

## Usage

```
transitive.closure(g, mat=FALSE, loops=TRUE)
```

## **Arguments**

g graphNEL object or adjacency matrix.
mat convert result to adjacency matrix.
loops Add loops from each node to itself?

#### **Details**

This function calculates the transitive closure of a given graph. We use the matrix exponential to find the transitive closure.

### Value

returns a graphNEL object or adjacency matrix

32 transitive.projections

#### Author(s)

Florian Markowetz <URL: http://genomics.princeton.edu/~florian>

#### See Also

```
transitive.reduction
```

### **Examples**

```
V <- LETTERS[1:3]
edL <- list(A=list(edges="B"), B=list(edges="C"), C=list(edges=NULL))
g <- new("graphNEL", nodes=V, edgeL=edL, edgemode="directed")
gc <- transitive.closure(g, loops=FALSE)

par(mfrow=c(1,2))
plot(g, main="NOT transitively closed")
plot(gc, main="transitively closed")</pre>
```

transitive.projections

Computes the transitive approximation of a directed graph

## Description

Computes the transitive approximation of a graph. The transitive approximation of a graph is a graph that is "almost" transitively closed and has minimal distance to the input graph.

### Usage

```
transitive.projections(adjmat)
```

## Arguments

adjmat

graphNEL object or adjacency matrix.

#### Value

returns adjacency matrices and having minimal graph distance to the input graph matrix

#### Author(s)

Juby Jacob

#### See Also

```
transitive.projections
```

transitive.reduction 33

```
transitive.reduction
```

Computes the transitive reduction of a graph

### **Description**

transitive.reduction removes direct edges, which can be explained by another path in the graph. Regulation directions inferred via infer.edge.type are taken into account.

#### Usage

```
transitive.reduction(g)
```

#### **Arguments**

g

adjacency matrix

## **Details**

transitive.reduction uses a modification of the classical algorithm from the Sedgewick book for computing transitive closures. The so-called "transitive reduction" is neither necessarily unique (only for DAGs) nor minimal in the number of edges (this could be improved).

#### Value

returns an adjacency matrix with shortcuts removed

## Author(s)

Holger Froehlich

## References

R. Sedgewick, Algorithms, Pearson, 2002.
